## DECLARATION OF ORIGINALITY

#### Abstract

I declare that this report entitled "PERFORMANCE OF DIFFERENT OPERATION TECHNIQUES APPLIED IN GENETIC ALGORITHM TOWARDS BENCHMARK FUNCTIONS" is my own work except as cited in the references. The report has not been accepted for any degree and is not being submitted concurrently in candidature for any degree or other award.

Date

## ACKNOWLEDGEMENTS

I would like to express my sincere thanks and appreciation to my supervisor, Dr. Lim Seng Poh who has given me this bright opportunity to engage in Artificial Intelligence related project. For your patience and guidance, unconditional support and love, a million thanks to you.

Finally, I must say thanks to my parents and my family for their love, support and continuous encouragement throughout the entire course.

#### Abstract

Optimisation problem becomes a popular topic because it is able to optimise the resources available. The importance of using optimisation in solving the case studies has been revealed by researchers in the past. In addition, Genetic Algorithm (GA) is also become an interesting topic in this highly competitive world as it is able to solve the optimisation problem. However, the performance of GA is always not considered by the researchers due to the limited of knowledge of this area. So, this project aims to analyse different operation techniques in GA and identify the best combination of operation techniques in GA. 4 selection, 3 crossover, 3 mutation and 2 replacement operation techniques are applied and tested using 10 benchmark functions along with different parameters setting. Besides that, number of genes and number of maximum generation are also included in order to explore that whether the parameters setting will affect the performance of GA. Therefore, this project presents the importance on the combinations of different operation techniques in GA. After conducted the experiments, the best operation techniques for each operation was determined respectively. Tournament Selection performs better compared to the others selection operation techniques. Uniform Crossover and Flipping Mutation are the best operation techniques in their operations. The best replacement operation is Weak Parent Replacement. The experimental result shown that GA68 model contains this type of combination. It is concluded that GA68 model is the best GA model compared to the other GA models. Furthermore, this GA model is also able to perform well and obtain a good result when the parameters setting of the optimisation problem have been modified. The result produced from this project is able to assist the researchers to gain a better understanding of GA and apply the appropriate GA model in carrying out their research.

## CHAPTER 1 INTRODUCTION

## Chapter 1 Introduction

### 1.1 Project Background

Optimisation problem becomes a popular topic and a concerning area to be examined in this highly competitive modern world. This is due to optimisation is able to reduce the cost and maximise the profit of an organisation. Basically, given a function and input within a range of value for the optimisation problems, it can be either in maximisation or minimisation. It will reflect the selection on the best solution towards the problem given. Therefore, optimisation is able to produce the best possible result which is required to increase competitiveness against other competitors. According to Ghose (2002), bracketing methods, region elimination and gradient methods are used to solve the optimisation problem in the mathematical fields. However, these mathematical methods have several weaknesses such as stuck in suboptimal solution, may not be efficient in solving many problems, and also takes longer time to get the optimal solution. In order to overcome these weaknesses, Artificial Intelligence (AI) method is proposed to solve the optimisation problems.

As stated by Sivanandam and Deepa (2008), in the field of computer science, the optimisation problem is always solved using AI methods such as Evolutionary Computing (EC), Evolutionary Strategies, and Swarm Intelligence (SI). This is because AI methods offer several practical advantages including the simplicity, flexibility and robust to dynamic changes. Genetic Algorithm (GA) is one of the popular EC methods used to solve the optimisation problem which is proposed by John Holland in 1975. When GA is used to solve the same optimisation problem, its performances along with the optimal result could be obtained. However, Lim \& Haron (2013) have shown that different GA performances and optimal result can be obtained when different operation techniques are applied. Therefore, the result is considered to be the optimal when it is exactly or approximate towards the actual minimum. This method was further developed and now it is useful for solving the complicated optimisation problems such as timetabling and games playing.

## CHAPTER 1 INTRODUCTION

### 1.2 Problem Statement

The main purpose of the optimisation problems is to obtain the best result with the available resources. As stated in the previous section, mathematical methods require longer time to solve the optimisation problems. Thus, GA is applied to simplify the process and handle the optimisation problems. However, most of the previous works only applied GA without considering its performance. As stated by Lim and Haron (2013), the performance of GA are affected when different operation techniques are implemented in GA. Furthermore, as concluded by Reeves and Rowe (2002), the parameters setting is also one of the factors which can affect the performance of GA. In order to find the most appropriate GA to be implemented for a problem, a lot of testing has to be carried out with different combinations of operation techniques and parameters setting. For some of the previous works, the performance of GA is not considered in their case studies. This is due to the authors contain limitation of research time and lack of background knowledge on GA. Therefore, the performance of GA with different combination of operation techniques along with different parameters is explored in this project.

### 1.3 Project Objectives

This project aims to determine the performance of GA using benchmark functions. The main objectives of this project are intended to accomplish:

1. To analyse different operation techniques in GA.
2. To identify the best combination of operation techniques in GA using benchmark functions along with different parameters setting.

### 1.4 Project Scope

The scope of this project is stated as follows:

1. Only focus on 4 selection operation techniques, 3 crossover operation techniques, 3 mutation operation techniques and 2 replacement operation techniques. Hence, there are 72 combinations of operation techniques, as known as GA model.
2. Parameter settings (number of genes and number of maximum generation) are considered in this project.
3. The termination criteria applied in this project is maximum generation.
4. 10 benchmark functions as stated in Section 2.10 are used as the fitness functions in this project.
5. $\mathrm{C}++$ programming language is used in this project.

### 1.5 Impact, Significance and Contribution

As mentioned in the problem statement, the performance of GA is not considered in most of the case studies. This will lead to the case study takes longer time to be completed and may not obtain the best result when the authors are using the inappropriate GA on their case studies. Due to the increasing application of GA in solving the optimisation problem, the performance of GA is an important factor that should be considered. To reduce the consuming time of a research and improve the efficiency of the research, the performance of different GA models must be studied before employing it to the research.

In this project, GA is explored and the best combination of operation techniques in GA is identified. Through this project, the performance of different combinations of operation techniques in GA is determined using benchmark functions. Therefore, the contribution of this project is the result produced can be the reference for the other authors in the future. They can utilise the appropriate GA models to improve the performance of their research.

## CHAPTER 1 INTRODUCTION

### 1.6 Project Organisation

The project organisation is described as follows:
Chapter 2 will introduce GA including the background of GA, flow of GA and the basic operations in GA. In addition, the benchmark functions will be listed as well and some previous works which is related to GA will also be discussed in this chapter.

Chapter 3 will focus on the research methodology of this project and introduce the methods and technologies involved for a clearer view to this project.
Chapter 4 will present the analysis and discussion on the experimental result.
Chapter 5 will conclude the works and results from this project. Future works for this project is also discussed at the end of this chapter.

## Chapter 2 Literature Review

### 2.1 Overview

Nowadays, GA is proved to be one of the effective methods in solving the optimisation problems. As shown in the previous works, GA is able to obtain the good results for different kind of case studies. This chapter is structured as follows: the introduction along with the flow of GA is discussed in the second section. In addition, introduction of benchmark functions is demonstrated. Besides, previous work is thoroughly discussed in the last section.

### 2.2 Introduction to GA

According to Sivanandam and Deepa (2008), GA was proposed as a heuristic method based on "Survival of the fittest" by John Holland in 1975. This idea was inspired by the theory of natural evolution in the origin of species and it was further developed in the book "Adaptation in natural and artificial systems." Similar to Genetic Programming and Evolutionary Strategy, GA is based on the principle of genetics and evolution. Basically, GA is a stochastic algorithm, it contains randomness in its process as stated by Sivanandam and Deepa (2008).

As stated by Engelbrecht (2002), GA has terms of chromosomes or individuals which represent a solution for the problems. In order to determine the quality of a solution, the solution is evaluated using fitness function and a fitness value is obtained. Generally, fitness function models the optimisation problems. Initial population represents the entire search space of the optimisation problems, has to be generated at the beginning of GA. Several operations including selection, crossover, mutation and replacement, will be performed on the initial population. Based on the work of Lim and Haron (2013), several techniques in each operations can be chosen to be applied in order to meet the conditions of the optimisation problems. The initial individuals will be replaced by the new generated individuals which have a better fitness value. A search termination will be defined to stop the GA and the last generation represents the optimum solution that the GA finds. Hence, the performance of the GA in solving different problems is affected by the techniques applied in each operation. As mentioned by Seng and Gun (2016), the number of parents also affects the performance of Multi-Parent GA. The flow of GA is explored in the next section.

### 2.3 Flow of GA

Figure 2.3.1 Flow of Genetic Algorithm

The flow is stated as below:

1. An initial population of chromosomes is generated based on the range given.
2. The chromosomes are then evaluated using the fitness function and the fitness value is determined.
3. In selection, a children is produced by 2 sets of chromosomes which are randomly selected from the population.
4. In crossover, the crossover only happens when a generated random number is less than the crossover probability. Else, the crossover would not happens and proceed to the next operation.
5. In mutation, the mutation only happens when a generated random number is less than the mutation probability. Else, the mutation would not happens and proceed to the next operation.
6. The children are then evaluated using the fitness function.
7. If the children's fitness value is higher than the parents, the parent is replaced by children. Else, check for the termination criteria.
8. If the termination criteria is met, the algorithm is terminated. Else, continue to step 3.

### 2.4 Selection Operation

According to Sivanandam and Deepa (2008), selection is the process of choosing two individuals (known as parent) from the current population to perform crossover. The selection techniques are used in this project including Roulette Wheel Selection, Random Selection, Rank Selection, and Tournament Selection.

### 2.4.1 Roulette Wheel Selection

This technique functions similar to the roulette wheel, by assigning a slot to each individual in the roulette wheel, so every individual stands a chance to be chosen as parent. However, the weights of each individual's slot are different, it scales to the individual's fitness value. The higher the fitness value of an individual, the bigger the slot of the individual occupies, and the higher the chance of being chosen as the parent. Figure 2.4.1 illustrates the process of roulette wheel selection.

Figure 2.4.1 Roulette Wheel Selection

### 2.4.3 Rank Selection

This technique selects two random individuals from the population. The individual with higher fitness value will be chosen as the parent. Figure 2.4.3 illustrates the process of rank selection.

Figure 2.4.3 Rank Selection

### 2.4.4 Tournament Selection

This technique selects a random number of individual for a competition. The winner of the competition which has the highest fitness value among all the competitors will become the parent. Figure 2.4.4 illustrates the process of tournament selection.

Figure 2.4.4 Tournament Selection

### 2.5 Crossover Operation

As Sivanandam and Deepa (2008) noted, crossover is the process of taking two parents generated from the selection and producing two individuals (known as child). The crossover happens based on the crossover probability. In this project, Single Point Crossover, Two Point Crossover and Uniform Crossover are used in the crossover operation.

## CHAPTER 2 LITERATURE REVIEW

### 2.5.1 Single Point Crossover

In this technique, a random position along the length of the chromosome is generated and it will be the crossover point. In the chromosome of child 1 , the section before the crossover point will be exactly same as parent 1 and the section after the crossover point will be same as parent 2 . In the chromosome of child 2 , the section before the crossover point will be same as parent 2 and the rest will be same as parent 1. Figure 2.5.1 illustrates the process of single point crossover.

### 2.5.2 Two Point Crossover

This technique randomly selects two positions to become the crossover points. The section between the starting point and the first crossover point of child 1 will be copied from parent 1 , the section from the first crossover point to the second crossover point will be taken from parent 2 , and the section from the second crossover point to ending point will be copied from parent 1 . Child 2 works in the opposite way. Figure 2.5.2 illustrates the process of two point crossover.

## Single Point Crossover

| Parent 1:1 2 4 3 5 6 2 5 4 1 |
| :--- |
| Parent 2:5 1 2 1 2 3 4 5 2 |

Child 2: | 5 | 1 | 2 | 1 | 2 | 6 | 2 | 5 | 4 | 1 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

Crossover point

Figure 2.5.1 Single Point Crossover

Figure 2.5.2 Two Point Crossover

## CHAPTER 2 LITERATURE REVIEW

### 2.5.3 Uniform Crossover

In this technique, a binary crossover mask is generated. The length of the mask is same as the length of chromosome. If the value of the mask's position is 1 , child 1 copies the chromosome from parent 1. Else, child 1 copies the chromosome from parent 2 . Child 2 works in the opposite way. Figure 2.5.3 illustrates the process of uniform crossover.

```
Uniform Crossover
Parent 1: \1 2 2 4 4 3 3 5 5:6
```

```
Mask : \0 0
```

```
Child 2: 14 1.|
```

Figure 2.5.3 Uniform Crossover

### 2.6 Mutation Operation

Sivanandam and Deepa (2008) have concluded that mutation is the process to change the value of an individual's genes to a random value within the range given. The mutation happens based on the mutation probability and the purpose of mutation is to prevent the GA to be trapped in a local minimum. The mutation operations such as Flipping, Interchanging, and Reversing are used in this project.

### 2.6.1 Flipping

In this technique, a random value is generated in order to replace the old value of a gene. Figure 2.6.1 illustrates the process of flipping mutation.

Figure 2.6.1 Flipping

### 2.6.2 Interchanging

Two different and random genes of the chromosome are selected, and the values of the positions are interchanged. Figure 2.6.2 illustrates the process of interchanging mutation.

Figure 2.6.2 Interchanging

### 2.6.3 Reversing

A random gene of the chromosome is chosen, and the value next to that position is reversed. Figure 2.6.3 illustrates the process of reversing mutation.

Figure 2.6.3 Reversing

### 2.7 Replacement Operation

As Sivanandam and Deepa (2008) stated, replacement is the process to return the better fitness value individuals to the population. The purpose of replacement is to ensure the better individuals will be stayed in the population. Random Replacement and Weak Parent Replacement are applied in this project.

### 2.7.1 Random Replacement

The children replace two randomly chosen individuals in the population without considering the fitness value. Hence, an individual with the higher fitness value may be replaced in this technique. Figure 2.7.1 illustrates the process of random replacement.

Figure 2.7.1 Random Replacement

## CHAPTER 2 LITERATURE REVIEW

### 2.7.2 Weak Parent Replacement

The children only replace their parent when the parent's fitness value is lower than their children's fitness value. In this technique, the individuals with the lower fitness value will not be inserted into the population. Figure 2.7.1 illustrates the process of weak parent replacement.

Figure 2.7.1 Random Replacement

### 2.8 Search Termination

As Sivanandam and Deepa (2008) mentioned, Search Termination is the condition which stops the GA from continue producing new generation. Maximum generation is frequently used as the search termination criteria, as shown in Lim and Haron (2013). Hence, it is applied in this project.

### 2.9 Parameters in GA

Population size is the total of individuals in the population for one particular generation. Number of genes is the total gene of an individual contains. Figure 2.9.1 illustrates the relationship of population, individual and genes.

Figure 2.9.1 Population, Individual and Gene in GA

Crossover probability is the probability of a crossover happens in generating new individuals. Mutation probability is the probability of a mutation happens in the genes of an individual. According to Lim and Haron (2013), the suitable crossover probability is 0.7 and suitable mutation probability is 0.01 . The reason of high crossover probability is to make the children have more chances to be different from its parents and a better new individual could be generated. The reason of low mutation probability is to preserve the good genes of an individual from changing. Hence, the values mentioned above are used in this project.

In this project, number of generation is the total iteration of performing a whole series of operation techniques. Number of testing is the total of testing for each GA model in optimising every benchmark functions. 30 testing for each GA model in every benchmark functions are performed in this project.

### 2.10 Benchmark Functions

In this project, 10 benchmark functions are used as the fitness function. These benchmark functions are minimisation problems and they are typical standard functions to test the performance of GA model. As stated by Molga \& Smutnicki (2005), the common characteristics of benchmark functions is a single global optimum exists in each benchmark function and some benchmark functions might have huge number of local optimum. Therefore, benchmark functions are good case studies for identifying the performance of GA models in performing optimisation since GA is intended to find the global optimum value. The benchmark functions are referred from the work done by Surjanovic and Bingham (2017) and Lim and Haron (2013). Benchmark functions are stated as follows:

1. Ackley function
$f(x)=20+\exp (1)-20 \exp \left(-0.2 \sqrt{\frac{1}{n} \sum_{i=1}^{n} x_{i}^{2}}\right)-\exp \left(\frac{1}{n} \sum_{i=1}^{n} \cos \left(2 \pi x_{i}\right)\right)$
$-30 \leq x_{i} \leq 30, i=1, \ldots, n$
Global minimum, $f(x)=0$ for $x_{i}=0, i=1, \ldots, n$
$n$ is the number of dimension
2. Axis parallel hyper-ellipsoid function
$f(x)=\sum_{i=1}^{n} i x_{i}^{2}$
$-5.12 \leq x_{i} \leq 5.12, i=1, \ldots, n$
Global minimum, $f(x)=0$ for $x_{i}=0, i=1, \ldots, n$ $n$ is the number of dimension
3. Sum of different powers function
$f(x)=\sum_{i}^{n}\left|x_{i}\right|^{i+1}$
$-1 \leq x_{i} \leq 1, i=1, \ldots, n$
Global minimum, $f(x)=0$ for $x_{i}=0, i=1, \ldots, n$ $n$ is the number of dimension
4. Rotated hyper-ellipsoid function
$f(x)=\sum_{i=1}^{n} \sum_{j=1}^{i} x_{j}^{2}$
$-65.536 \leq x_{i} \leq 65.536, i=1, \ldots, n$
Global minimum, $f(x)=0$ for $x_{i}=0, i=1, \ldots, n$ $n$ is the number of dimension
5. Sphere function
$f(x)=\sum_{i=1}^{n} x_{i}^{2}$
$-5.12 \leq x_{i} \leq 5.12, i=1, \ldots, n$
Global minimum, $f(x)=0$ for $x_{i}=0, i=1, \ldots, n$ $n$ is the number of dimension
6. Rastrigin function
$f(x)=10 n+\sum_{i=1}^{n}\left(x_{i}^{2}-10 \cos \left(2 \pi x_{i}\right)\right)$
$-5.12 \leq x_{i} \leq 5.12, i=1, \ldots, n$
Global minimum, $f(x)=0$ for $x_{i}=0, i=1, \ldots, n$ $n$ is the number of dimension

## 7. Zakharov function

$f(x)=\sum_{i=1}^{n} x_{i}^{2}+\left(\sum_{i=1}^{n} 0.5 x_{i}\right)^{2}+\left(\sum_{i=1}^{n} 0.5 x_{i}\right)^{4}$
$-5 \leq x_{i} \leq 10, i=1, \ldots, n$
Global minimum, $f(x)=0$ for $x_{i}=0, i=1, \ldots, n$
$n$ is the number of dimension
8. Schwefel 22 function
$f(x)=\sum_{i=1}^{n}\left|x_{i}\right|+\prod_{i=1}^{n}\left|x_{i}\right|$
$-10 \leq x_{i} \leq 10, i=1, \ldots, n$
Global minimum, $f(x)=0$ for $x_{i}=0, i=1, \ldots, n$
$n$ is the number of dimension
9. Griewank function
$f(x)=\sum_{i=1}^{n} \frac{x_{i}^{2}}{4000}-\prod_{i=1}^{d} \cos \left(\frac{x^{i}}{\sqrt{i}}\right)+1$
$-600 \leq x_{i} \leq 600, i=1, \ldots, n$
Global minimum, $f(x)=0$ for $x_{i}=0, i=1, \ldots, n$ $n$ is the number of dimension
10. Quartic with noise function
$f(x)=\sum_{i=1}^{n} i x_{i}^{4}+$ random $[0,1)$
$-1.28 \leq x_{i} \leq 1.28, i=1, \ldots, n$
Global minimum, $f(x)=0$ for $x_{i}=0, i=1, \ldots, n$
$n$ is the number of dimension

### 2.11 Previous Works

According to Lim and Haron (2013), different GA methods contain its advantages and limitations while dealing with the problems. It is concluded that none of the GA methods can perform perfectly on every problems. In this work, the performance of 2 GA with different operation techniques was compared using the 5 benchmark functions and it provided a detailed report regarding the experimental result. However, it is not enough to conclude the performance of 2 GA models by only implementing 5 benchmark functions. According to the result from this previous work,

GA is proved to perform well in the optimisation problems but the performance highly depends on the applied techniques in each operation.

Another work from the previous two authors, Lim and Haron (2013), compared the performance of GA, Differential Evolution (DE) and Particle Swarm Optimisation (PSO) towards benchmark functions. In this work, it proved that different results are obtained by different methods even though the parameters setting is same. This work applied 3 different methods towards the benchmark functions and compared them in details. However, the result are unable to justify the performance of GA because it is compared with different types of methods.

Ebraheem and Jyothsna (2015) carried out the comparison of performance of teaching learning based optimisation (TLBO) against GA on benchmark functions. TLBO is a consistent optimisation algorithm which is proposed by Rao et al. in 2011. 'The TLBO method is based on the effect of influence of a teacher on the output of learners in the class' (Ebraheem and Jyothsna, 2015). Similar to the previous work mentioned above, the result is not able to justify the performance of GA because it compared GA with TLBO instead of among different operation techniques of GA. However, the result of comparing GA with TLBO is well obtained through this work and it concluded that TLBO performs better and obtains result faster than GA.

As suggested by Madhu et al. (2016), GA can be applied for minimisation of execution time for cloudlets through optimal allocation of virtual machines. To ensure availability and reliability of services provided by the cloud services provider, the virtual machines have to be placed in different location. Hence, GA is used to optimise the allocation of the virtual machines. In this work, the roulette wheel selection and tournament are used as the selection techniques. However, only one operation technique from crossover, mutation and replacement operation were applied and the relevant techniques were not mentioned. This limits the optimisation problem from getting the most optimal result while only one combination of GA is considered.

Bazi, Benzid, and Nait Said (2017) have applied GA and Firefly Algorithm (FA) to find the optimised proportional integral (PI) controller design in permanent magnetic synchronous motor (PMSM). In this case study, there is a limitation of GA encountered which is trapping in a local minimum. This degrades the performance and reduces the search capability. Furthermore, FA produces more accurate results and takes less computation time. However, the details of operation techniques of both algorithm were
not clearly mentioned in this case study. Based on the result, they concluded FA is better than GA from the aspects of time computing, results quality and robustness.

According to the work done by $\mathrm{Du}, \mathrm{Li}$ and Xu (2016), GA is used to resolve antenna selection for massive multiple-input multiple-output (MIMO) system. MIMO is a technique in 5G and it can produce higher power efficiency than 4G. Hence, the MIMO will be widely implemented in different location. However, the cost of implementing a new MIMO is expensive. Therefore, antenna selection becomes an important issue for reducing the cost while maintaining the performance of the system. In this work, GA is proved to perform well, faster and more practical than other exhaustive method. However, the fitness function was only tested by one GA, so it was not tested by other operation techniques than proposed GA. The performance of other GA could be better than the proposed. In order to get the optimum result for this problem, the combinations of GA operation techniques have to be applied as much as possible.

GA is used in the work of Badge and Gurjar (2016) to recognise the free handwritten style in Marathi script. In this related work, it included image acquisition, image preprocessing, feature extraction, classification and GA. The purpose of this work is to compare the performance of existing techniques with GA. Similar to the previous work mentioned, only one GA was applied to solve the problem. However, the work stated that the optimality of the results obtained using GA is affected by the population and number of iteration. Furthermore, the issues of applying GA included finding a suitable type of representation which is either binary coding or value coding, creating the right fitness function, choosing appropriate combination of GA operation techniques and the specific probability value for crossover and mutation.

As suggested by Boonyopakorn and Meesad (2017), GA is used to solve university time table problems. Generally, the problems of this previous work included allocations and distribution of resources to different task related to different constraints. The operation techniques were performed are tournament techniques as the selection, uniform crossover as the crossover operation, and the chromosome only mutates to a chromosome exactly same as a random existing and valid parent. In addition, this previous work applied four different methods which are GA, Immune Genetic Algorithm (IGA), Particle Swarm Optimisation (PSO) and Artificial Immune System (AIS), and combined them as a hybrid approach to solve the timetabling problem. The authors combined the strengths of each method through hybrid approach. Their work
proved that the hybrid approach was able to improve the quality of initial solutions and provide a nearly optimal solution. However, there were only one technique applied in each operation, this limited the performance of the experiment, and the best combination of operation techniques which should be applied in this case study might be ignored.

Most of the previous works show that GA is suitable to be applied in different types of case studies. When GA is incorporated in the case study, it is able to produce the optimum result. However, those previous works do not consider on the performance of the GA. Actually the techniques in each of the operation can affect the overall result of GA, no matter in terms of minimisation or maximisation. Therefore, this project focuses on the performance of GA with different combinations of operation techniques using benchmark functions.

### 2.12 Summary

This chapter explored the background of GA along with the benchmark functions. Different previous works were discussed in order to understand how GA is incorporated with the case studies. Therefore, 10 benchmark functions are used in this project as the fitness function and tested with different combinations of GA. The result produced from the testing phase is analysed in order to make comparison among the different operation techniques.

## Chapter 3 Research Methodology

### 3.1 Overview

Research methodology helps to identify the main stages of the research. A good research methodology addresses potential issues in research and helps the researchers to coordinate and focus the research effort. This chapter will discuss the methodology of this project.

### 3.2 Research Framework

The research framework as shown in Figure 3.2.1 is applied in this project described as follows.

Figure 3.2.1 Research Framework
The main outcome of this project is to propose a good combination of GA operation techniques by comparing the performance of different combinations of GA operation techniques towards the benchmark functions. In addition, two extra experiments with different parameters setting are conducted to provide further justification to the performance of GA models. In order to compare the performances among the GA, a lot of coding and testing are performed. The duration of this project is approximately 20 weeks.

## CHAPTER 3 RESEARCH METHODOLOGY

### 3.2.1 Analysis Phase

Analysis phase is the very first and crucial stage of this project. In analysis phase, the GA concepts, parameters in GA and benchmark functions are studied. In addition, the data collection is conducted during this phase and the data are intended to be randomly generated based on the range of the benchmark functions. To explore the existing solutions and determine the strengths and weaknesses of them, the reviews on the related works of this project are carried out. After reviewing the related works, the project objectives and scopes are defined as the guidelines of this project.

### 3.2.2 Design Phase

The design phase is carried out by designing and developing the code for the project. In this phase, the operation techniques of GA are further explored and new requirements or constraints are defined. For example, a new requirement which is number of generation changes in different experiments. In addition, the hardware and software specifications, and technology framework are identified in the design phase. In this project, MS Visual Studio 2015 is used to perform experiment with C++ programming language.

This section discusses on the details of GA models and parameters setting. As mentioned in the previous chapter, there are 4 selection operation techniques, 3 crossover operation techniques, 3 mutation operation techniques and 2 replacement operation techniques in this project. Table 3.2.2.1 shows the operation techniques in this project.

| No. | Selection | Crossover | Mutation | Replacement |
| :--- | :--- | :--- | :--- | :--- |
| 1. | Roulette Wheel | Single Point | Flipping | Random |
| 2. | Random | Two Point | Interchanging | Replacement |
| 3. | Rank | Uniform | Reversing |  |
| 4. | Tournament |  |  |  |

Table 3.2.2.1 Operation Techniques in GA
In this project, there are 72 combinations of operation techniques are tested towards the benchmark functions. Table 3.2.2.2 shows example for the combination of operation techniques. The complete table has been displayed in Appendix A.

| GA model | Selection |  |  |  | Crossover |  |  | Mutation |  |  | Replacement |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 3.2.2.2 Example of GA Models with Combinations of Different Operation Techniques

As shown in Table 3.2.2.2, GA1 model consists of roulette wheel selection, single point crossover, flipping mutation and random replacement.

In this project, there are 6 parameters which manipulates the result of testing. The parameters setting in Experiment 1 is adapted from Lim and Haron (2013). Experiment 2 and 3 are the additional testing to test the performance of GA. In Experiment 2 and 3, the parameters which are number of gene and number of generation, are modified. This project intends to test whether the performance of GA will be affected by the parameters setting and how will it be affected. Table 3.2.2.3 shows the parameters setting for each experiment.

| No. | Parameter | Value |  |  |
| :--- | :--- | :---: | :---: | :---: |
|  |  | Experiment 1 | Experiment 2 | Experiment 3 |
| 1. | Population Size | 40 | 40 | 40 |
| 2. | Number of Genes | 30 | 10 | 30 |
| 3. | Crossover Probability | 0.7 | 0.7 | 0.7 |
| 4. | Mutation Probability | 0.01 | 0.01 | 0.01 |
| $\mathbf{5 .}$ | Number of Generation | 2000 | 2000 | 10000 |
| $\mathbf{6}$ | Number of Testing | 30 | 30 | 30 |

Table 3.2.2.3 Parameters Setting in Different Experiments
In this project, several tools, software and hardware are utilised to conduct the experiment. The details of tools are listed below, and the hardware specification is shown in Table 3.2.2.4 and the software specification is shown in Table 3.2.2.5.

Microsoft Visual Studio Community 2015

- Microsoft Visual Studio 2015 is an integrated development environment (IDE) from Microsoft, which is a commonly used tools to develop computer programs. Furthermore, Microsoft Visual Studio 2015 has many build-in libraries which provides support in developing the program in this project.

## Notepad

- Notepad is a simple text editor for Microsoft Windows. The output produced from the program is saved using this program.

Microsoft Excel 2013

- Microsoft Excel is a spreadsheet developed by Microsoft for Windows, which performs calculation and tabling. Microsoft Excel 2013 provides support to the work of making statistics of the performance of GA models.

## Hardware Specification

| Hardware | Description |
| :--- | :--- |
| Processor | ${\text { Intel® } \text { Core }^{\mathrm{TM}} \text { i5-5200U } 2.20 \mathrm{GHz}}^{\text {RAM }}$ |

Table 3.2.2.4 Hardware Specification

## Software Specification

| Software | Description |
| :--- | :--- |
| Operating System | Windows 8.1 64-bit |
| Development Tool | Microsoft Visual Studio Community 2015 |
| Documentation Tool | Notepad <br> Microsoft Excel 2013 |

Table 3.2.2.5 Software Specification

### 3.2.3 Implementation Phase

In the implementation phase, the coding of different operation techniques and benchmark functions is conducted successively. Furthermore, the coding is revised and the correctness of the coding is proved in this phase.

### 3.2.4 Testing Phase

After building a program which is able to perform all operation techniques and benchmark functions, the program is tested using white box testing technique. The coding of benchmark functions are tested by comparing the actual result with the expected result. Furthermore, each operation technique and the integration of operation techniques are also tested in this phase. After proving that the program is free from major defects, the experiment is conducted using this program to test the performance of the GA using the data which is randomly generated in the analysis phase. Thus, the performance of different GA towards the benchmark functions are determined by running the program and a good algorithm is found out by comparing the performances.

### 3.2.5 Documentation Phase

The output produced from the previous phase are documented in the documentation phase. In addition, the documentation includes the description of GA operation techniques, benchmark functions and parameters setting used in this project. Analysis on the result and comparison of GA models are conducted in this phase.

### 3.3 Implementation Issues and Challenges

The main challenge in this project is the coding of the algorithm has to be developed well, otherwise the overall performance of the algorithm will be affected. In addition, there are 72 combinations of operation techniques which are needed to be considered and experimented. Hence, this project consumes a lot of time in coding and testing phase.

Besides, the parameter settings is an important issue since it is the important factor of affecting the performance. The value of each parameter has to be ideal in order to get an optimal result.

### 3.4 Timeline

Analysis phase and design phase are the crucial phases in FYP 1. Literature review on GA and the exploration of algorithms in GA are needed to be performed in order to understand the background of this project. Furthermore, partial of coding is conducted in FYP1.

In FYP2, implementation phase, testing phase and documentation phase are the important phases. The coding is further improved and tested to test the GA models towards the benchmark functions. In addition, the result obtained from the experiments is saved and used to perform the analysis and discussion. The details of analysis and discussion are well documented in documentation phase.

### 3.4.1 FYP1 Gantt chart

Figure 3.4.1.1 shows the timeline of FYP1. FYP1 consists of analysis phase, design phase and part of implementation phase.

Figure 3.4.1.1 Gantt chart of FYP1

### 3.4.2 FYP2 Gantt chart

Figure 3.4.1.2 shows the timeline of FYP1. FYP2 consists of design phase, implementation phase, testing phase and documentation phase.

Figure 3.4.1.2 Gantt chart of FYP2

### 3.5 Summary

In this project, the program is written in C++ language using Microsoft Visual Studio Community 2015. Furthermore, this project is divided into 5 phases which are analysis phase, design phase, implementation phase, testing phase and documentation phase. By following the schedule of 5 phases, this project is able to be conducted and completed on time.

## Chapter 4 Analysis and Discussion

### 4.1 Overview

Analysis and discussion are needed to identify the best combination of operation techniques in GA. The result from the executed program is collected and analysis is performed based on the result obtained. Hence, the analysis and discussion on the performance of GA models towards benchmark functions are included in this chapter.

### 4.2 Experimental Result

After the execution of code in the testing phase, the result of each GA model towards the benchmark functions is obtained. Average fitness value is the main criterion used to evaluate the performance of each GA model and the computation time is not considered in this project. This is because this project is focused on the optimisation towards the actual optimum for each benchmark function. Hence, the accuracy is more important than the speed of algorithm.

This section shows the result obtained from Experiment 1, Experiment 2 and Experiment 3. The result in Experiment 1, Experiment 2 and Experiment 3 which consists of minimum fitness value, average fitness value and average of time taken is shown in Appendix B. The following three simplified tables are focusing on the average of fitness value of the benchmark functions using 72 GA models in Experiment 1, Experiment 2 and Experiment 3.

Table 4.2.3 Average Fitness Value of Benchmark Functions in Experiment 3

BCS (Hons) Computer Science
Faculty of Information and Communication Technology (Perak Campus), UTAR.

In the tables, B1 is referred as Benchmark Function 1 in Section 2.10 and GA01 is referred as GA model 1 in Table 3.2.2.2. The applied operation techniques in each GA model is derived from the table in Appendix A and the respective parameters setting of each experiment is mentioned in Section 3.2.2.

In next section, only the top 10 GA models for each benchmark function in each experiment are discussed. The top 10 GA models as stated in this project is determined and evaluated using the average values as shown in Table 4.2.1 to Table 4.2.3. There are the lowest and minimum compared to the others GA models. This proves that their performance is greater than the others 62 GA models in each benchmark function.

In the following tables, occurrence shows the total of existence for a particular GA model appeared in the top 10 GA models of benchmark functions. However, the more occurrence of a particular GA model does not determine its performance is better than the others. For example, a GA model appears 9 times in the top 10 list but all of them occupy the lower ranking of GA models and another GA model appears only 5 times but all of them occupy the upper ranking of GA models. Hence, the performance of GA models is calculated using weighting and rating method, suggested by James. In order to distinguish the importance of each rank, different weighting is assigned respectively. Even though this method is subjective and personal bias, it is effective to gain a quantitative answer.

The weight is assigned in the range from 0 to 1 . Top 1 is the best among all the ranking. Hence, it should be assigned with the highest weight, which is 1.0 . For Top 2, it is higher compared to the other ranking, but it is lower compared to Top 1. Therefore, it is assigned with 0.9 , which is slightly lower than the weight of Top 1 . The remaining ranking are assigned according to this criteria. As for Top 10, it is the weakest among the ranking. However, it is still able to achieve in Top 10 compared to the remaining 62 GA models, so it is assigned with 0.1 instead of 0.0. Table 4.2 .4 shows the weight of each ranking.

| Ranking | Top <br> $\mathbf{1}$ | Top <br> $\mathbf{2}$ | Top <br> $\mathbf{3}$ | Top <br> $\mathbf{4}$ | Top <br> $\mathbf{5}$ | Top <br> $\mathbf{6}$ | Top <br> $\mathbf{7}$ | Top <br> $\mathbf{8}$ | Top <br> $\mathbf{9}$ | Top <br> $\mathbf{1 0}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Weight | 1.0 | 0.9 | 0.8 | 0.7 | 0.6 | 0.5 | 0.4 | 0.3 | 0.2 | 0.1 |

Table 4.2.4 Weight of Ranking

The performance calculation is as derived using the formula as stated below. The higher the percentage of the performance, the better the GA model in solving the optimisation problem.

$$
\begin{equation*}
\text { Performance of GA model, } f(x)=\frac{\sum_{i=1}^{10} x_{\text {top } i} \times \text { weight }_{\text {top } i}}{\text { total occurrence of GA model }} \times 100 \% \tag{1}
\end{equation*}
$$

Where,
$x$ is the occurrence of GA model
top $i$ is the ranking of GA model
total occurrence of GA model $=10$

### 4.3 Analysis and Discussion for Experiment 1

This section includes the analysis and discussion for Experiment 1. Based on the result of Experiment 1 shown in Table 4.2.1, top 10 GA models for each benchmark functions are identified. Table 4.3.1 shows the 10 best GA models in solving each benchmark function. Table 4.3 .2 shows the occurrence and performance of GA models in Experiment 1. The calculation for Performance (\%) is derived using Formula (1).

Table 4.3.3 shows the operation techniques on top 10 GA models.

| Benchmark Functions | GA Models Ranking in Experiment 1 |  |  |  |  |  |  |  |  |  |

Table 4.3.3 Operation Techniques of Top 10 GA Models in Experiment 1

Based on Table 4.3.1, GA68, GA56, GA62, GA14, GA38, and GA50 have occurred 10 times followed by GA44, GA32, and GA67 with 9 occurrence which represents these GA models have good performance in solving every benchmark function. Among the GA models that have occurred 10 times, GA68 has been the Top 1 GA model for 8 out of 10 benchmark functions, GA62 has been the Top 2 GA model for 6 out of 10 benchmark functions and GA56 has been the Top 3 GA model for 6 out of 10 benchmark functions. Hence, GA58, GA56 and GA62 are the top 3 best GA models in Experiment 1.

### 4.3.1 Selection Operation Technique Perspectives

Among those GA models, 5 of them are Tournament Selection, 3 of them are Rank Selection, 3 of them are Roulette Wheel Selection, and 2 of them are Random Selection. As mentioned above, GA68, GA56, and GA62 are the top 3 GA models in Experiment 1. Based on Table 4.3.3, the selection operation technique of these three GA models is Tournament Selection. This shows that Tournament Selection has the best performance compared to other selection operation techniques. The second best selection operation technique is Rank Selection. Roulette Wheel Selection is the third. Last, Random Selection has the worst performance among these four selection operation techniques. However, the difference of occurrence of each selection operation technique is not much. This shows that technique used in selection operation is not the main factor that affecting the performance of a GA model.

Tournament Selection and Rank Selection are similar. They randomly choose a number of individual to be involved into a competition and then, the higher fitness value individual is chosen as the parent. The difference between them is the size of the
competition. In Rank Selection, there are only two individuals are selected for the fitness value comparison. On the other hand, Tournament Selection usually select more than two individuals for the competition pool, two-thirds of the population is selected into the competition pool in this project. The more the individuals included in the competition pool, the higher the chances of selecting a high fitness value individual as the parent. However, using Tournament Selection, it has a higher chance to select same individual as the parent in different generations. This reduces the chances of selecting the other individuals as it has a good gene but not high fitness value and produces similar individuals in the population which results the stuck in local optimum. On the other side, Rank Selection is able to prevent the quick convergence as the ability to select different individual as the parent.

In Roulette Wheel Selection, every individual occupies different area of slice in the roulette wheel based on its fitness value and the area of slice represents its probability to be selected as a parent. If the fitness value of an individual is higher, the slice given to this individual will be larger. In this technique, every single individual stands a chance to be selected and this may introduce the weaker individual as the parent. However, the limitation of this technique is if an individual has a big lead of fitness value than others, then the weaker individuals will have very small area of slices. This causes the weaker individuals have very less chances for being selected. Last, Random Selection is the worst technique among these four selection operation techniques. Random Selection selects an individual as the parent without considering its fitness value. The advantage of this technique is every individual has the equal chance to be selected. Hence, it is able to introduce a weaker individual which might contains a good gene as the parent and increase the population diversity. However, Random Selection slows down the evolution of the population and not able to obtain an optimum result when weak children is produced in each generation.

The best selection operation technique is Tournament Selection and the other selection operation techniques also have a good performance in solving different optimisation problems.

### 4.3.2 Crossover Operation Technique Perspectives

Based on Table 4.3.2, all of the crossover operation techniques have appeared for similar number of occurrence. This shows that crossover has less effect to the performance of GA models compared to other operation techniques. However, there is a pattern of the occurrence of crossover operation techniques. Uniform crossover always performs better than other two crossover operation techniques when the GA models contains exactly the same operation techniques. The second best is the Two Point Crossover and the last is Single Point Crossover.

The purpose of crossover is to produce a stronger child by copying the good genes from its parent. Single Point Crossover separates the genes of the individual into two parts and exchanges one part with the part from another individual. The advantages of this technique are the children are less diverse and similar to their parents. When the population has evolved enough generation, good fitness value individuals are produced in the population. Single Point Crossover is good at this situation because it is able to keep the good genes for the children while performing the crossover. On the other hand, Single Point Crossover needs more iterations to produce a good individual since it provides low diversity of population. Two Point Crossover is similar to Single Point Crossover, it has one more crossover point. This makes the children is more diverse and able to produce a good individual at a faster pace than Single Point Crossover.

Uniform Crossover is proved as the best crossover operation technique based on the result of Experiment 1. Uniform Crossover generates a binary crossover mask to determine which genes it should copy from the respective parent. Uniform Crossover produces a more diverse and very different children from the parents. The advantages of this technique are a stronger individual is introduced faster compared to the other two crossover operation techniques and the diversity of population increases. Hence, the best fitness value individual is not able to remain as the best for too long unless it reaches the optimum value. As mentioned above, in the later generation, good genes are desired to be kept inside an individual. Uniform Crossover could separate the good genes into two children and children with lower fitness value are produced.

Crossover operation is not the major factor of affecting the performance of GA models. Based on the analysis, Uniform Crossover is the best crossover operation technique followed by Two Point Crossover and Single Point Crossover.

### 4.3.3 Mutation Operation Technique Perspectives

From Table 4.3.3, it shows that top 10 GA models for every benchmark functions are using Flipping Mutation. Interchanging and Reversing are totally not included in the top 10 GA models.

Mutation operation alters the value of the genes to prevent the GA to be trapped in the local optimum. Flipping Mutation changes the value of the genes from the initial value into a new randomly generated value. This might make the individual to have a better fitness value. The disadvantage of this technique is if the new value is worse than the initial value, then a worse fitness value individual is produced.

Interchanging Mutation and Reversing Mutation do not generate a new value to replace the initial value but swapping the position of the genes. In Interchanging Mutation, the value of two genes is swapping to the position of each other. In Reversing Mutation, the value of a gene and next to it is reversing ascending order or descending order. These two mutation operation techniques do not make any difference in the value of genes. The effect of these two mutation techniques happens while performing crossover in next iteration. For example, if all the individual of a population are similar, a different child will be produced by swapping the value of genes. The limitation of these two mutation operation techniques is not able to escape from the local minimum when the genes of the best individual are similar.

Based on the result, mutation operation is the major factor of affecting the performance of GA models towards the benchmark functions. Flipping has a better performance compared to Reversing and Interchanging.

### 4.3.4 Replacement Operation Technique Perspectives

Most of the top 10 GA models are using Weak Parent Replacement. Hence, it proves that Weak Parent Replacement is better than Random Replacement. The main reason is Weak Parent Replacement always replaces the weaker parents with the stronger children and Random Replacement randomly selects an individual to be replaced. In this case, Weak Parent Replacement is able to keep good individuals in the population. On the other hand, Random Replacement might replace a good individual with a worse child and this prevents the GA model from getting more optimal result. In addition, a better individual does not always have the best genes. Sometimes, the worse individual might have a better gene compared to a better individual but the other worse genes inside that individual cause its low fitness value. So, the worse individual with
the best gene will be replaced. This situation can be potentially avoided using Random Replacement since it performs the replacement randomly but not based on the fitness value. However, this is not effective since the worse individual with the best gene still stands a chance to be replaced using Random Replacement.

Based on the result, replacement operation is one of the major factors of affecting the performance of GA models towards the benchmark functions. Weak Parent Replacement always performs better than Random Replacement.

### 4.3.5 Findings on Experiment 1

Based on the result from Experiment 1, Tournament Selection, Uniform Crossover, Flipping Mutation and Weak Parent Replacement is the best combination of operation techniques. These operation techniques are included in GA68 and it works well in most of the benchmark functions.

### 4.4 Analysis and Discussion for Experiment 2

This section includes the analysis and discussion for Experiment 2. The changes parameters setting in Experiment 2 is stated in Table 3.2.2.3. Based on the result of Experiment 2 shown in Table 4.2.2, top 10 GA models for each benchmark functions are identified. Table 4.4 .1 shows the 10 best GA models in solving each benchmark function in Experiment 2. Table 4.4.2 shows the occurrence and performance of GA models in Experiment 2. The calculation for Performance (\%) is derived using Formula (1). Table 4.4 .3 shows the operation techniques on top 10 GA models.

| Benchmark Functions | GA Models Ranking in Experiment 2 |  |  |  |  |  |  |  |  |  |

Table 4.4.3 Operation Techniques of Top 10 GA Models in Experiment 2

### 4.4.1 Parameter Setting Perspectives

Experiment 2 alters the number of genes from 30 to 10. The dimension of the population in Experiment 2 is $40 \times 10$. Hence, the diversity of the population is low.

By comparing the result from Table 4.2.1 and Table 4.2.2, the fitness values are dropping drastically and nearer to the optimum values. The main reason is the most of the benchmark functions are summation, so the less the dimension of population, the lower the fitness value of the benchmark functions.

From Table 4.3.3 and Table 4.4.3, the ranking of selection operation, mutation operation and replacement operation is similar. The main difference of these two tables is the crossover operation. In Experiment 2, Two Point Crossover has outperformed Single Point Crossover compared to Two Point Crossover has similar performance to Single Point Crossover in Experiment 1. As mentioned above, the diversity of population in Experiment 2 is low, this makes Two Point Crossover could outperform Single Point Crossover since Two Point Crossover provides more diversity for the children.

### 4.4.2 Findings on Experiment 2

In Experiment 2, GA68 is still the best GA model in solving optimisation problems with Tournament Selection, Uniform Crossover, Flipping Mutation and Weak Parent Replacement. Furthermore, Single Point Crossover is not a suitable technique to be used when the number of genes is less.

### 4.5 Analysis and Discussion for Experiment 3

This section includes the analysis and discussion for Experiment 3. The changes parameter setting in Experiment 3 is stated in Table 3.2.2.3. Based on the result of Experiment 3 shown in Table 4.2.3, top 10 GA models for each benchmark functions are identified. Table 4.5 . 1 shows the 10 best GA models in solving each benchmark function in Experiment 3. Table 4.5 .2 shows the occurrence and performance of GA models in Experiment 3. The calculation for Performance (\%) is derived using Formula (1). Table 4.5.3 shows the operation techniques on top 10 GA models.

| Benchmark Functions | GA Models Ranking in Experiment 3 |  |  |  |  |  |  |  |  |  |

Table 4.5.3 Operation Techniques of Top 10 GA Models in Experiment 3

### 4.5.1 Parameter Setting Perspectives

In Experiment 3, the altered parameters setting is the maximum generation, which increases from 2,000 to 10,000 . By comparing the performance of operation techniques, GA68 is still the best model in this experiment.

The best fitness value of each benchmark function obtained from this experiment is nearer to the optimum value compared to the result obtained in Experiment 1. The difference of the best fitness value between these two experiments is actually big. Hence, maximum generation has a great influence on the final fitness value of the population. Number of the generation determines how many evolutions the population could have. The more the evolutions, the better the final fitness value of a population.

### 4.5.2 Findings on Experiment 3

In Experiment 3, GA68 is still the best GA model in solving optimisation problems with Tournament Selection, Uniform Crossover, Flipping Mutation and Weak Parent Replacement. In addition, number of maximum generation is a major factor of affecting the fitness value of benchmark functions.

### 4.6 Overall Experimental Result and Findings

In this section, the result of three experiments are combined together to see the overall performance. The result as shown in Table 4.3.2, Table 4.4.2 and Table 4.5.2 are merged by summation and shown in Table 4.6.1. Due to the compilation of three experimental results, the total occurrence of GA model is replaced with 30 in Formula (1) because the total occurrence of each GA model able to appear in 10 benchmark function is 30 . Table 4.6 .1 shows the total occurrence and performance of GA models in three experiments.

| GA <br> Model | Ranking in Three Experiments |  |  |  |  |  |  |  |  |  | Occurrence | Performance (\%) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Top 1 | Top 2 | Top 3 | Top 4 | Top 5 | Top 6 | Top 7 | Top 8 | Top 9 | Top 10 |  |  |

| GA67 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 7 | 3 | 10 | 5.67 |
| GA20 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 4 | 1 | 7 | 6.67 |
| GA26 | 0 | 0 | 1 | 2 | 0 | 2 | 0 | 1 | 3 | 4 | 13 | 15.00 |
| GA02 | 1 | 2 | 1 | 1 | 0 | 0 | 2 | 1 | 1 | 2 | 11 | 19.33 |
| GA08 | 2 | 1 | 3 | 0 | 1 | 0 | 2 | 1 | 6 | 10 | 26 | 30.67 |
| GA38 | 0 | 0 | 3 | 1 | 0 | 0 | 1 | 16 | 6 | 2 | 29 | 32.33 |
| GA32 | 3 | 0 | 0 | 0 | 2 | 7 | 7 | 5 | 1 | 2 | 27 | 41.33 |
| GA44 | 0 | 0 | 1 | 3 | 12 | 3 | 3 | 4 | 1 | 0 | 27 | 47.33 |
| GA14 | 2 | 1 | 1 | 3 | 3 | 12 | 6 | 1 | 0 | 1 | 30 | 54.67 |
| GA50 | 0 | 6 | 4 | 9 | 3 | 1 | 5 | 0 | 0 | 1 | 29 | 64.33 |
| GA56 | 1 | 6 | 9 | 6 | 1 | 3 | 0 | 1 | 1 | 0 | 28 | 68.00 |
| GA62 | 2 | 13 | 5 | 3 | 4 | 1 | 1 | 0 | 0 | 0 | 29 | 77.00 |
| GA68 | 19 | 1 | 2 | 2 | 3 | 0 | 3 | 0 | 0 | 0 | 30 | 86.33 |

Table 4.6.1 Occurrence of GA Models in the Experiments
From Table 4.6.1, GA68 is the best GA model among all the combinations of operation techniques. GA68 has the best performance for 19 out of 30 benchmark functions testing. This shows that GA68 is able to fully optimise most of the benchmark functions. GA62, GA56 and GA50 are also having great performance towards the benchmark functions. GA14, GA44 and GA32 are mainly appearing in the middle ranking. Most of the appearance of GA32 and GA08 are in lower ranking. From this information, the priority of selecting operation techniques can be derived. For example, in GA68, GA62 and GA56, most of the operations are same and the only different GA operation is the crossover. GA68 is Uniform Crossover, GA62 is Two Point Crossover, and GA56 is Single Point Crossover. This shows that crossover operation is the main factor of affecting the performance in the upper ranking GA models. In other word, crossover operation has the least influence in affecting the performance of GA models since it only influence the ranking when the other operation techniques remain the same. From Table 4.3.3, mutation operation is the most important operation, followed
by replacement operation and selection operation, and the least important operation is crossover operation.

### 4.7 Summary

Based on the analysis and discussion above, GA68 has been concluded as the best combination of operation techniques with Tournament Selection, Uniform Crossover, Flipping Mutation and Weak Parent Replacement. However, other GA models could outperform GA68 in certain circumstances such as decreases the dimension of population and increases the number of maximum generation. In this project, two additional distinct experiments are conducted with different parameters setting which are the number of gene and number of maximum generation. Through the comparison between the results of three experiments, it is concluded that parameters setting are able to indirectly affect the performance of GA models. The operation that the most affecting the performance of GA model is the mutation. Hence, the selecting of mutation operation techniques should be considered first in implementing GA in the research.

## Chapter 5 Conclusion and Future Works

Optimisation problem is a concerning topic in this highly competitive modern world. By solving the optimisation problem, an organisation is able to minimise the cost and maximise the profit. Common methods used to solve the optimisation problem are mathematical methods and AI methods, and GA is one of the popular AI methods. In GA, there are few techniques on different operation and the performance of GA model is affected by the techniques applied. Most of researchers do not consider the performance of GA in their works. In consequence, the researchers are unable to obtain the optimum result and take longer time to get result. Hence, it is important to explore the combinations of different operation techniques and test their performance. By identifying the performance of each combination, this helps the researchers as a guideline to select an appropriate GA model and improve the efficiency and accuracy of their research.

This project aims to analyse the operation techniques and identify their performance of solving optimisation problems. Based on the experiments result, different operation techniques applied will affect the performance of the GA model. As discussed in the previous section, the best GA model is identified based on the ability of optimising the benchmark functions. Furthermore, GA68 which consists of Tournament Selection, Uniform Crossover, Flipping Mutation and Weak Parent Replacement, is concluded as the best GA model after running the experiments. GA68 is still able to have the best performance among the GA models with the changes of parameters setting. However, other GA models are slightly affected.

To improve the performance of GA towards the optimisation problem, other operation techniques can be tested and parameters setting can be modified. The identified good GA models are can also be implemented in different case studies and more benchmark functions to further prove their good performance. In addition, the best GA model determined in this project will be used to compare with the others mathematical and optimisation methods.

Performance of Different Operation Techniques Applied in Genetic Algorithm Towards Benchmark Functions Ong Chin Hwa 1501696
Faculty of Information and Communication Technology (FICT) University Tunku Abdul Rahman.
Project Supervisor: Dr. Lim Seng Poh

## Project Overview

Genetic Algorithm is an important topic in this highly competitive world. This is because GA is able to solve the optimisation problem. The importance of optimisation has been revealed by people in past. Nowadays, optimisation helps to reduce cost and increase profit. However, the performance of GA is always not considered by the researcher due to the lack of knowledge and time consuming. Therefore, this project will present the importance on the combinations of different operation techniques in GA.

## Problem Statement

i. Researchers are not able to obtain optimum result due to lack of knowledge in GA.
ii.Performance of GA will be affected when different operation techniques are implemented in GA.

## Project Objectives

i. To analyse different operation techniques in GA.
ii. To identify the best combination of operation techniques in GA using benchmark functions along with different parameter settings.

## Project Scope

i. 4 Selection Operations: Roulette Wheel, Random, Rank, Tournament
ii. 3 Crossover Operations: Single Point, Two Point, Uniform
iii. 3 Mutation Operations: Flipping, Interchanging, Reversing
iv. 2 Replacement Operations: Random, Weak Parent
v. 10 benchmark functions are used as fitness function vi. $\mathrm{C}++$ programming language is used

Flow of GA

## Result

Experiments with different parameter settings are conducted. The performance of each GA model toward benchmark functions is obtained. The best GA model consists of Tournament Selection, Uniform Crossover, Flipping Mutation and Weak Parent Replacement.

## Conclusion

By comparing the performance of different GA models, the best GA model will be determined. In addition, this provides support to the researcher in doing optimisation problem. This helps the researchers to improve the efficiency of their research.
