# ABSTRACT <br> ENHANCED SELF-ORGANISING MAP MODEL FOR SURFACE RECONSTRUCTION OF UNSTRUCTURED DATA 

You Cheng Chun

Surface reconstruction (SR) is a process of recovering the digital representation of an object in reverse engineering. When the unstructured data are applied in the SR process, incorrect surface is produced because the data do not have any connectivity information. Self-Organising Map (SOM) models were proposed to organise the unstructured data to regain the connectivity information, but incorrect surface with holes, internal neurons and different grid sizes problems were appeared. Although the SOM model can generate the correct surface, its output is not in the standard format of Computer Aided Geometric Design. So, Non-Uniform Rational B-Spline (NURBS) surface approximation approach was applied to the output using parameterisation methods. However, the surfaces generated still contain gaps and were not optimal. Hence, the surfaces can be optimised using optimisation techniques. Therefore, the objectives of this research are to propose a SOM model for organising the unstructured data and to present and optimise the NURBS surface approximation approach with Genetic Algorithm (GA), Differential Evolution (DE) and Particle Swarm Optimisation (PSO). The data set used includes four primitive objects and a medical image data. The codes were developed using Microsoft Visual Studio 2022 with C++ programming
and GNUPlot was used to visualise the results. The results shown that the Double Net SOM (DNSOM) model performed faster than 3-D SOM and Cube Kohonen SOM (CKSOM), achieved the lowest Topographic Error and generated the correct surface with fewer neurons compared to CKSOM. Additionally, the improved NURBS approach with Chord Length method was able to generate the correct surface with no gaps and the least surface error. DE can optimise the improved NURBS surface better compared to GA and PSO by achieving 243 out of 280 least optimised surface errors. The research outcomes can be utilised in reverse engineering to recover the surface of an object.

## ACKNOWLEDGEMENT

First and foremost, I would like to acknowledge the support of Ministry of Higher Education (MOHE) for funding this project under the Fundamental Research Grant Scheme (FRGS) with the grant number FRGS/1/2019/ICT02/UTAR/02/3. In addition, I would also like to acknowledge the support of Universiti Tunku Abdul Rahman (UTAR) in funding my research under UTAR Research Fund (UTARRF) Topup Scheme with the vote number 6235/L18.

Next, I would like to convey my deepest appreciation to my supervisor, Ts. Dr. Lim Seng Poh, for his professional advice and guidance throughout my journey as a Masters student. The completion of this project would not have been possible without him as someone who has always inspired and motivated me to do better in the work I pursued.

Special thanks go to my co-supervisor, Ts. Dr. Lee Cheng Kang, who was very attentive and patient in every meeting we conducted. The brilliant comments and suggestions he gave have been really useful to my project.

I would also like to express my heartfelt gratitude to my parents, You Ming Hai and Siew Swee Lian, for their unconditional support and encouragement. I am truly grateful to be born into this loving family and to have them as my parents.

Last but not least, I wish to extend my sincere thanks to my close friends whom I can share my ups and downs with throughout this research journey. Their accompaniment has made me mentally stronger to fight against challenges and keep helplessness and loneliness at bay.

## APPROVAL SHEET

This dissertation entitled "ENHANCED SELF-ORGANISING MAP MODEL FOR SURFACE RECONSTRUCTION OF UNSTRUCTURED DATA" was prepared by YOU CHENG CHUN and submitted as partial fulfillment of the requirements for the degree of Master of Science (Computer Science) at Universiti Tunku Abdul Rahman.

Approved by:

(Ts. Dr. Lim Seng Poh)
Date: $15^{\text {th }}$ November 2023
Supervisor
Department of Computer Science,
Faculty of Information and Communication Technology, Universiti Tunku Abdul Rahman.

(Ts. Dr. Lee Chen Kang)
Date: $15^{\text {th }}$ November 2023
Co-supervisor
Department of Internet Engineering and Computer Science, Lee Kong Chien Faculty of Engineering and Science, Universiti Tunku Abdul Rahman.

## SUBMISSION OF DISSERTATION

It is hereby certified that You Chen Chum (ID No: 20ACM02161) has completed this dissertation entitled "Enhanced Self-Organising Map Model for Surface Reconstruction of Unstructured Data" under the supervision of Ts. Dr. Lim Sens Poh (Supervisor) from the Department of Computer Science, Faculty of Information and Communication Technology, and Ts. Dr. Lee Chen Kang (CoSupervisor) from the Department of Internet Engineering and Computer Science, Lee Kong Chien Faculty of Engineering and Science.

I understand that University will upload softcopy of my dissertation in pdf format into UTAR Institutional Repository, which may be made accessible to UTAR community and public.

Yours truly, h
(YOU CHENG THUN)

## DECLARATION

I hereby declare that the dissertation is based on my original work except for quotations and citations which have been duly acknowledged. I also declare that it has not been previously or concurrently submitted for any other degree at UTAR or other institutions.

Date: $15^{\text {th }}$ November 2023

## CHAPTER 1

## INTRODUCTION

### 1.1 Overview

Surface reconstruction is defined as a process of rebuilding a surface based on different input data, such as triangular mesh, set of structured or unstructured point clouds and intersection lines, whereby the surface generated must represent the original object's surface [1]. It is undeniably a very challenging task arising in various areas such as Computer-Aided Design (CAD) [2], medical imaging [3], [4], [5], geology [6], [7], [8], [9], [10], urban reconstruction [11] and reverse engineering [12], [13], [14], [15]. Thus, surface reconstruction in these areas is an ongoing and popular research that can be explored.

The surface reconstruction pipeline begins with the acquisition of the point clouds representing the geometry of scanned objects and surroundings [16]. The point clouds are acquired from depth cameras [17] or Light Detection and Ranging (LiDAR) sensors [18]. The data acquired in surface reconstruction can either be structured or unstructured [16]. It is important to identify them before choosing which surface reconstruction techniques to be used to reconstruct the surface of the collected data [19]. Structured data contain connectivity information while the unstructured data do not have any connectivity information [20], [21], [22]. Since unstructured data do not have any connectivity information, it is challenging to reconstruct the surface of the unstructured data because the data should be organised correctly to regain the
correct connectivity information among the data. The surface generated would be incorrect if the correct connectivity information among the data is not regained. In addition, a correct and smooth surface with minimum surface error should also be generated when reconstructing the surface of the unstructured data.

Various Self-Organising Map (SOM) models were utilised to organise the unstructured data. Structured data were produced when the SOM model organised the unstructured data correctly. However, the structured data are not in the standard format for Computer-Aided Geometric Design (CAGD) [23]. Parametric surface such as Non-Uniform Rational B-Spline (NURBS) is often used in CAGD due to its stability, flexibility and local modification properties. According to Knopf, Sangole and Archana [24], parametric surface fitting requires prior knowledge about the connectivity between the data. Since the connectivity information between the data is obtained after the data is organised, the parametric surface fitting can be applied on the organised data. Lim and Haron [25] proved that the NURBS surface approximation approach can be applied after the unstructured data was organised successfully.

Although the NURBS surface approximation approach is proven to be applicable to structured data, the NURBS surface generated is not the most accurate. Previous works [26], [27], [28], [29], [30], [31], [32] have shown that parametric curves and surfaces such as Bézier, B-Spline and NURBS can be optimised by adjusting their parameters to generate better curves and surfaces of the data with various optimisation techniques [33], [34]. Optimisation techniques that were used to optimise the parametric curve and
surface include Genetic Algorithm (GA) [26], [27], [35], [36], [37], Differential Evolution (DE) [28], [29] and Particle Swarm Optimisation (PSO) [30], [31], [32].

### 1.2 Problem Background and Statements

Previous works have shown that Self-Organising Map (SOM) models were used to regain the connectivity information of the unstructured data. The 2-D SOM model was utilised to organise the unstructured open surface data. Although the model can organise the unstructured open surface data, it fails to organise and generate the correct surface given the unstructured closed surface data. The surface generated contain holes [25], [42], [43]. To tackle this limitation, a SOM model was initialised as an icosahedron and undergone the subdivision process, is utilised to organise the unstructured closed surface data in [41]. Furthermore, a Deep Learning SOM (DLSOM) [42] model was introduced to organise the unstructured closed surface data. Apart from the 2D SOM model, the 3-D SOM model was not able to organise the unstructured data and generate the correct surface due to the existence of the internal neurons as highlighted in [25]. Hence, Cube Kohonen SOM (CKSOM) [25] was introduced to organise the unstructured closed surface data and to overcome the limitation of 2-D SOM and 3-D SOM models. Despite the strengths of the model, the length and width of its grid cannot be tuned with different values.

After the unstructured data was organised successfully by the SOM model, the data would be structured data. Several previous works [23], [28], [29], [32] represented the structured data with parametric surfaces via surface
approximation approach. In [32], B-Spline surface approximation was employed as the surface representation for the output of the growing grid SOM. Furthermore, NURBS surface approximation approach was employed in [28] on the output of the growing grid SOM. The NURBS surface approximation approach was also applied on the CKSOM model to represent the output of the model with the standard representation format for the CAGD [23]. However, the NURBS surfaces generated contain gaps at the boundary of the surface. Hence, the NURBS surface approximation approach should be improved to overcome the problem.

Although the surface approximation is applicable on the output of the SOM models as the surface representation, the surface generated may not represent the original data accurately. Hence, various optimisation techniques from the area of soft computing were utilised to optimise the parameters of the parametric curve or surface so that a curve or surface with minimum error can be generated. The parametric curve or surface can be utilised to optimise the parameters of the parametric curve or surface. GA was utilised in [26] to perform parameter optimisation for B-Spline curve fitting. Hierarchical GA was introduced in [27] to perform B-Spline surface approximation. Furthermore, parallel hierarchical GA [36] was constructed to approximate the B-Spline curve given the unstructured data by locating the optimal number and locations of the knots, and the control points of B-Spline simultaneously. Besides, DE was used to find the optimal control points for the Bézier curve [29]. DE was also applied on the growing grid SOM to optimise the NURBS surfaces [28]. In addition, PSO was employed in [32] to optimise the B-Spline surface representing the organised data of the growing grid SOM by finding
the optimal control points. In [30], PSO was utilised to obtain the optimal values for all the coefficients of NURBS given different 3-D data points.

Although various SOM models such as the 2-D SOM and 3-D SOM were proposed to organise the unstructured data, they are still suffering from limitations as stated in [25]. The limitations include holes problem in 2-D SOM [43] and connectivity problems in 3-D SOM [25]. Besides, it was identified that the length and width of the grid in CKSOM cannot be tuned with different value. So, to generate a surface that is similar to the original object, the unstructured data should be organised appropriately. Additionally, representing the structured data with suitable surface approximation is important in surface reconstruction because the surface produced by the SOM models is not the standard format in CAGD. However, gaps appeared when it was applied on the SOM model as shown in [23] which might cause higher surface error. So, the surface error can be optimised with the optimisation techniques as shown in [28], [32]. Therefore, the surface represented should achieve minimum surface error and similar to the original object.

### 1.3 Research Objectives

The objectives of this research are:
i. To propose a SOM model for organising unstructured data.
ii. To propose a surface approximation approach based on the proposed SOM model in representing the surface.
iii. To optimise the surface approximation approach through the implementation of GA, DE and PSO.

### 1.4 Research Scopes

The scopes of the research are stated as follows:
i) Data sets

- Four primitive shape data such as cube, sphere, spindle and oiltank [44], and a medical data which is talus bone [45] are the data sets used in this research. The four primitive shape data are used to show that the proposed SOM model, known as Double Net SOM (DNSOM) model can organise unstructured data, regain their connectivity information and apply on the medical data.
- The data sets are unstructured data in the form of coordinates $(x, y$, $z)$.
- Additional data set (Stanford bunny data [46]) is used in this research as an additional testing to further evaluate the model.
ii) Parameterisation methods
- The Uniform, Chord Length, Centripetal and Exponential are the only parameterisation methods considered to be applied in the improved NURBS surface approximation approach.
- Various sizes of control net (CN) are utilised to examine the performance of the parameterisation method.
iii) Optimisation
- GA with Tournament Selection, Uniform Crossover, Random Mutation and Weak Parent Replacement, DE [33] and PSO with velocity clamping and constriction factor [34] are the optimisation
methods applied on the control points of the improved NURBS surface approximation approach to minimise the surface error.
iv) Performance Measurements
- Minimum and maximum errors, Quantisation Error (QE), Topographic Error (TE) and CPU time are used in the first objective to evaluate the performance of the 2-D SOM, 3-D SOM, CKSOM and DNSOM models. There is no ground truth available because SOM model is an unsupervised learning model [146].
- Surface error based on Euclidean distance [23] and the concept of the DNSOM model in second objective was utilised to measure the performance between the surface approximation approaches and parameterisation methods.
- Optimised surface error based on Euclidean distance and concept of the DNSOM model was used in third objective to evaluate the performance between the optimisation techniques.
v) Visualisation
- GNUPlot is used to visualise the data sets and the results of the first, second and third objective.

### 1.5 Dissertation Organisation

This dissertation comprised of seven chapters. The organisation of this dissertation is as follows. Chapter 1 provides a general overview and the problem background and statements of this research. This chapter also highlights the objectives and the scope of this research. Chapter 2 reviews the related works. Various Self-Organising Map (SOM) models, parametric
curves and surfaces such as B-Spline and Non-Uniform Rational B-Spline (NURBS) are reviewed in Chapter 2. Apart from that, optimisation techniques such as GA, DE and PSO are also reviewed in Chapter 2. Chapter 3 demonstrates the research methodology of this research. This chapter also includes the hardware and software used in this research.

Meanwhile, Chapter 4 describes the system flow of DNSOM model, analyses and discusses the performance of the DNSOM model. Chapter 5 explains the steps of the improved NURBS surface approximation approach. Besides, Chapter 6 describes the system flow of the optimisation techniques applied to optimise the improved NURBS surface approximation approach and this Chapter also analyses and discusses the performance of the optimisation techniques. Chapter 7 provides the conclusion of this research. The limitations, future works and contributions of this research are also presented in this chapter.

## CHAPTER 2

## LITERATURE REVIEW

### 2.1 Overview

This chapter discusses the process and data in surface reconstruction. The existing surface reconstruction techniques, surface representation and surface approximation in surface reconstruction are discussed thoroughly in this chapter. This chapter also reviewed the existing optimisation techniques.

### 2.2 Surface Reconstruction

Surface reconstruction is the process of retrieving the data through the scanning of objects and reconstructing the surface of the retrieved data [19]. The process and data involved in surface reconstruction are discussed in this section.

### 2.2.1 Process

The process in surface reconstruction consists of parameterisation and surface approximation [30], [32], [47]. Parameterisation is a process of generating the parameters that define the relationship among the surface data and surface approximation is the process of fitting the surfaces according to the parameter values of the parameterisation [32]. In [23], [32], data are organised initially and the data are presented with the free-form parametric surface through parameterisation and surface approximation after the data are organised. Besides, the free-form parametric surface in [32] was optimised with optimisation technique to produce a more accurate surface. In [30], optimisation technique is used to perform both parameterisation and surface
approximation on the data which are unstructured to generate a correct surface with high accuracy. Therefore, these previous works show that the data determine how the parameterisation and surface approximation is performed because structured data with rectangular topology can be applied with parametric surfaces by performing parameterisation and surface approximation as a linear problem but unstructured data would have to apply the parametric surfaces as a complex high-dimensional non-linear optimisation problem.

### 2.2.2 Data

Data in surface reconstruction are collected through the scanning of the existing objects with depth cameras [17] or Light Detection and Ranging (LiDAR) sensors [18]. The data collected can be in the form of structured or unstructured [48]. Data with connectivity information are known as structured data. Meanwhile, data without any connectivity information are known as unstructured data [49]. When both of the data are used in surface reconstruction, a correct surface would be produced for the structured data and an incorrect surface would be produced for the unstructured data because structured data have the connectivity information among the data but the unstructured data do not have any connectivity information among the data. Thus, the unstructured data need to be organised correctly so that the correct connectivity information among the data can be obtained and a correct surface can be produced. It is important to obtain the correct connectivity information for the unstructured data because the reconstructed surface relies on it [16]. The structured data can be presented with the parametric surface through parameterisation and surface approximation. Besides, other properties of the
data such as noise, sampling density, misalignment, outliers and missing data have the impact in surface reconstruction [50]. These data make the task of computing a surface representation that resembles the original object and retaining their critical surface features a very challenging task [51].

### 2.3 Surface Representation and Approximation

Explicit and implicit are the two types of surface representation [52]. Triangulated and parametric surfaces are the two types of explicit surfaces [19]. Triangulated surface was generated with Voronoi diagram (VD) and its dual, Delaunay triangulation (DT) techniques such as Crust [68], Cocone [69], Power Crust [70], SuperCocone [71], Tight Cocone [72] and Localised Cocone [73]. However, most of the techniques are not robust towards noisy and non-uniform data. In contrast, implicit surface is generated by initially define an implicit function and extract the zero-level iso-surface. Then, the zero-level iso-surface can be visualised through ray casting and marching cube [53]. The implicit function can be a signed distance function [54], [55], [56], [57], [58], radial basis function (RBFs) [59], [60], [61], piecewise polynomial functions [62], indicator functions [63], [64], [65] or wavelets [66], [67]. Besides, parametric surface can be generated through surface interpolation or approximation. Surface approximation generates the surface better than the surface interpolation because surface approximation generates the surface that approximate the data points, minimising the surface error, whereas the surface interpolation generates the surface that passes through all the data points [74], [75]. This makes the surface approximation to be more robust towards data with noise and the surface interpolation to be sensitive to data with noise [76]. Surface approximation can minimise the influence of the noise in the data [76].

Surface interpolation would generate a surface that interpolates the incorrect data point when the data has noise [76]. Surface approximation is performed after the parameter values of the data is computed through parameterisation. A good parameterisation is essential to determine the connectivity among the data in the surface parametric domain, and the topology and boundaries of the surface [30]. Data with rectangular topology is required for the parametric surface because parametric surface use such data as input [77]. Hence, the method used to organise the unstructured data must have the rectangular topology. The parametric surface is used primarily in the computer-aided geometric design (CAGD) [78] because they have a great flexibility and can represent any smooth shape well [74].

### 2.3.1 Parametric Representation on B-Spline and Non-Uniform Rational B-Spline

The parametric representation is referred to the representation of the data with free-form parametric curves and surfaces such as B-Spline and Non-Uniform Rational B-Spline (NURBS). This section discusses the mathematical formulation of the B-Spline and NURBS curves and surfaces. B-Spline curves and surfaces were introduced due to the global influence of the control points in Bézier curve and surface [76], [79]. The entire curve or surface will be affected when a single control point was adjusted. The B-spline curve with $n+$ 1 control points $P_{i}(i=0, \ldots, n)$ and degree $p$ is defined as follows [80]:

$$
\begin{equation*}
C(t)=\sum_{i=0}^{n} N_{i, p}(t) P_{i} \tag{2.1}
\end{equation*}
$$

where $N_{i, p}(t)$ are the normalised B-Spline basis function defined on a knot vector $T=\left\{t_{0}=\ldots=t_{p}=0, t_{p+1}, \ldots, t_{n}, t_{n+1}=\ldots=t_{n+p+1}=1\right\}$. The knot vector
$T$ consists of non-decreasing real numbers knots on the interval $[0,1]$. The first and last knots of $T$ are usually repeated with multiplicity equal to degree $p$ $+1 . N_{i, p}(t)$ can be defined as follows [81], [82]:

$$
\begin{gather*}
N_{i, 0}(t)= \begin{cases}1 & \text { if } t_{i} \leq t<t_{i+1} \\
0 & \text { otherwise }\end{cases}  \tag{2.2}\\
N_{i, p}(t)=\frac{t-t_{i}}{t_{i+p}-t_{i}} N_{i, p-1}(t)+\frac{t_{i+p+1}-t}{t_{i+p+1}-t_{i+1}} N_{i+1, p-1}(t) \tag{2.3}
\end{gather*}
$$

The B-spline surface of degrees $(p, q)$ with $(m+1) \times(n+1)$ control points is defined as follows:

$$
\begin{equation*}
S(u, v)=\sum_{i=0}^{m} \sum_{j=0}^{n} N_{i, p}(u) N_{j, q}(v) P_{i, j} \tag{2.4}
\end{equation*}
$$

where $P_{i, j}$ is the control points, $p$ and $q$ are the degree of the surface in $u$ - and $v$-direction, $N_{i, p}(u)$ and $N_{j, q}(v)$ are the normalised B-spline basis functions given the knot vectors $U=\left\{u_{0}=\ldots=u_{p}=0, u_{p+1}, \ldots, u_{n}, u_{n+1}=\ldots=u_{n+p+1}=1\right\}$ and $V=\left\{v_{0}=\ldots=v_{q}=0, v_{q+1}, \ldots, v_{m}, v_{m+1}=\ldots=v_{m+q+1}=1\right\}$ in $u$ - and $v$ direction respectively.

NURBS is also one of the most common surface representations in real world applications [30]. A NURBS curve of degree $p$ is defined as follows [83], [84]:

$$
\begin{equation*}
C(u)=\frac{\sum_{i=0}^{n} N_{i, p}(u) w_{i} P_{i}}{\sum_{i=0}^{n} N_{i, p}(u) w_{i}} \tag{2.5}
\end{equation*}
$$

where $C(u)$ represents a point on the NURBS curve at $u, P_{i}$ are the control points, $w_{i}$ are the corresponding weights of the control points $P_{i}, N_{i, p}(u)$ are the normalised B-Spline basis function and $n+1$ is the number of control points.

A NURBS surface of degree $(p, q)$ with $(n+1) \times(m+1)$ control points is defined as follows [83], [84]:

$$
\begin{equation*}
S(u, v)=\frac{\sum_{i=0}^{n} \sum_{j=0}^{m} N_{i, p}(u) N_{j, q}(v) w_{i, j} P_{i, j}}{\sum_{i=0}^{n} \sum_{j=0}^{m} N_{i, p}(u) N_{j, q}(v) w_{i, j}} \tag{2.6}
\end{equation*}
$$

where, $u$ and $v$ are the parameter, $P_{i, j}$ is the $(i, j)$-th control points in 3-D space, $w_{i, j}$ is the corresponding weight of $P_{i, j}, N_{i, p}(u)$ and $N_{j, q}(v)$ are the $i$-th and $j$-th BSpline basis functions of degree $p$ and degree $q$ defined on knot vectors $U$ and $V$ in the $u$ - and $v$-direction respectively which is computed recursively with Equation 2.3.

One of the important properties of the NURBS surface is that the four corners of the NURBS surface data interpolates the four corner control points [147]. The difference between the NURBS and the B-Spline is the existence of weight associated to each control points. By setting the weight of all the control points in Equations 2.5 and 2.6 to 1.0, the NURBS curve and surface becomes a B-Spline curve and surface respectively [85]. The weight associated to each control point influences the NURBS curve or surface [86]. When the weight of a control point increases, the point on the NURBS curve or surface will move towards the corresponding control point or vice versa [81].

However, it is challenging to perform curve or surface approximation with NURBS because it is a non-linear problem as there are more than one unknown variable such as control points and their weight needed to be computed. Other than the control points and their weight, the parameters and knot vectors are also considered as unknown variables in [30]. Various previous works were proposed to perform curve and surface approximation
with NURBS. A two-step linear approach [85] was proposed in which the weights were initially identified with symmetric eigenvalue decomposition to solve the non-linear problem. After the weights were identified, the weights were used to compute the control points. Furthermore, a weights iterative optimisation technique for NURBS curve fitting was introduced in [81] to obtain the optimal weights with the least square method. In [23], [29], [37] SOM models with rectangular topology were used to organise the unstructured data and surface approximation was performed on the output of the models. The NURBS surfaces can be applied on the output of the SOM models with rectangular topology because the NURBS surfaces use such data as input [77]. Other than the influence of weight on the NURBS curve and surface, the parameterisation of the data points also influences the accuracy of NURBS curve and surface obtained [26].

### 2.3.2 Parameterisation and Surface Approximation

Parameterisation is a process of defining the relationship among the data and surface approximation is the process of fitting the surfaces according to the parameter values of the parameterisation [29]. Parameterisation is an important process because it influences the performance of the NURBS curve and surface approximation as shown in [87], [23] as different parameterisation methods would produce different parameter values and the parameter values reflect the distribution of the data. Appropriate parameterisation is required to obtain a good surface approximation [47]. The most commonly used parameterisation methods are Uniform, Chord Length, Centripetal and Exponential parameterisation methods [84], [23], [87], [88]. Uniform method is the simplest method [87] because the parameter values are computed
without the data points. Parameter values are computed from the Uniform method by utilising the definition in 2.7 [89]:

$$
\begin{equation*}
t_{i}=\frac{i}{n}, 1 \leq i \leq n-1 \tag{2.7}
\end{equation*}
$$

where $t_{0}=0$ and $t_{n}=1$ are the first and last parameters, $t_{k}$ is the middle parameters, $n$ is the index of the last point. The Chord Length method produces better results compared to the Uniform method if the data point is distributed non-linearly [95]. Meanwhile, the Centripetal method is an extension of the Chord Length method. By replacing the power factor, $\alpha$ in Equation 2.8 from 1.0 to 0.5 , the Chord Length method is extended to the Centripetal method. According to Iglesias et al. [148], the Centripetal method commonly yields better results than the Chord Length method for shapes with sharp turns. Exponential method was proposed in [88] by setting the power factor, $\alpha$ in Equation 2.8 to 0.8 . Parameter values are computed from the Centripetal, Exponential and Chord Length methods by applying $\alpha$ in Equation 2.8 with $0.5,0.8$ and 1.0 respectively [79], [89]:

$$
\begin{equation*}
t_{k}=\frac{\sum_{i=1}^{k}\left|Q_{i}-Q_{i-1}\right|^{\alpha}}{\sum_{i=1}^{n}\left|Q_{i}-Q_{i-1}\right|^{\alpha}}, k=1, \cdots, n-1 \tag{2.8}
\end{equation*}
$$

where $n+1$ is the total number of data points or total number of parameters, $t_{0}$ $=0$ and $t_{n}=1$ are the first and last parameters, $t_{k}$ is the middle parameters, $\left|Q_{i}-Q_{i-1}\right|$ is the distance between adjacent data points $Q_{i}$ and $Q_{i-1}, \alpha$ is the power factor and $L$ is the length of the data polygon.

The knot vector is generated after the parameter values are computed. Knot values can be generated with averaging knot vector method and it is defined as follows [79]:

$$
\begin{gather*}
T_{0}=T_{1}=\cdots=T_{p}=0  \tag{2.9}\\
T_{j+p}=\frac{1}{p} \sum_{i=j}^{j+p-1} t_{j}, j=1,2, \cdots, n-p  \tag{2.10}\\
T_{m-p}=T_{m-p+1}=\cdots=T_{m}=1 \tag{2.11}
\end{gather*}
$$

where $t$ is the knot vector. There would be $m+1$ knots, where $m=n+p+1$ for $n+1$ parameters with $t_{0}, t_{1}, \ldots, t_{n}$ with the degree $p$. This method was used in this research because it generates the knots according to parameter values.

Different parameterisation methods were used to compute the parameter values of various curve data for the B-Spline curve in [87] and the results show that the parameterisation methods do affect the results. Hence, the selection of an appropriate parameterisation methods is important for surface approximation [34]. In 2008, Forkan and Shamsuddin [32] represented the 3-D structured data of the growing grid SOM with B-Spline surface using the Centripetal method. Additionally, Zhang, Feng and Cui [90] conducted NURBS surface approximation with Chord Length method. Lim and Haron [23] proposed the use of NURBS surface approximation approach with different number of control points and parameterisation methods (Uniform, Chord Length, Centripetal) to represent the closed surface data of the Cube Kohonen Self-Organising Map (CKSOM) model. This approach would be applied in this research since it was proposed to be applied on multiple SOMs. Besides, NURBS was applied in [91] to approximate the surface of the data after the corner, boundary and interior points of the data are identified and classified using a deep neural network.

Based on the previous works [23], [32], parametric surface was applied on the unstructured data after the connectivity information among the data
were regained and the model used to organise the unstructured data in these previous works is Self-Organising Map (SOM) model. So, various SOM models were discussed in the next section.

### 2.4 Self-Organising Map Model

Self-Organising Map (SOM) [92] is an unsupervised learning neural network that performs dimensionality reduction by representing high-dimensional data with much lower dimensional space [93]. It was introduced by a Finnish professor Teuvo Kohonen [94]. The SOM contain neurons, arranged in triangular, rectangular or hexagonal topology [95], [96]. Each neuron is associated with a weight vector, which represents its location in the input space and has the same dimension as the input vectors [41]. Neurons with the smallest Euclidean distance between the weight and the input vectors is selected as the winning neuron [97]. Three main phases involved in the learning process of SOM are competition, cooperation and adaptation [98]. These phases will eventually update the weight vector of each neuron towards the input vectors. The common termination criterion employed in SOM is maximum number of iterations [99], [100], [101].

As shown in the previous works [41], [102], [103], [24], [42], [104], [105], [106], [22], [40], various SOM models were applied in surface reconstruction and the organisation of the unstructured data. Different SOM models were proposed to solve the problem of existing SOM models. In addition, improvements were made on the existing SOM models to increase their performance as shown in [103], [25]. In 1999, Hoffmann [103] made a modification on the SOM neighbourhood function by replacing the data type
of the return value from natural number to positive real number. The new function prevented the radius to decrease by 1 unexpectedly and gradually. The improvement helped to move the neurons closer to the input points. Consequently, a smoother surface was obtained. Furthermore, the 2-D SOM with rectangular structure, and a spherical SOM with the shape of an icosahedron and triangular mesh were used by Yu [41] to reconstruct the open and closed surface data respectively. Multiresolution learning and edge swap were suggested to learn the concave structures of an object. Although the suggested model can deal with the concave structures of the object, the use of edge swap is not user adaptive as it requires the user to shift the vertices of their incident triangles that are far away from the input data close to the input data. This action has to be repeated several times until the vertices reach a nearby input data.

Conformal self-organising map (CSM) [105] was proposed to provide conformal mapping to achieve the conformality requirement in the mapping of geometrical surface. The CSM and SOM were used to perform geometrical surface mapping on several data sets such as the 2-D uniformly-distributed square and 3-D half sphere, and their performances were evaluated with distortion error. Distortion error was calculated from the dimensionality reduction and quantisation errors. The CSM achieved lower distortion error when the total number of iterations increased indicating that the neurons in the CSM were updated nearer to the input data. However, the SOM generates the results faster than the CSM. Moreover, a conformal spherical self-organising map (CSSM), an extension of CSM was proposed to perform surface reconstruction of closed surface [104]. However, the surface produced was not
smooth due to the use of flat triangles to represent the CSM. A method was proposed [106] to construct a piecewise smooth seamless surface with special correspondence based on the derived surface of the CSM to produce a smooth surface.

The Kohonen learning rule was presented in [102] to perform the adaptation process. New neurons were added to increase the adaptation process at particular area. Besides, local subdivision task was on the identified problematic triangles and local adaptation process was applied on the subdivides area. With the approach, the issue of SOM in reconstructing concave regions is solved. Also, spherical SOM model was proposed in [24] to organise the unstructured data. The neurons in the spherical SOM were decorated with uniform triangles on a tessellated unit sphere. The Region-ofInfluence (ROI) procedure was adapted in the learning process of the model to generate a correct closed surface for object with concave areas and objects with holes. The procedure eliminates the need to refine the generated surface with mesh refinement transformations. However, this model was very vulnerable towards the density of the data [24]. Also, it might wrongly label the area of sparse data as intended holes and cause the model fit around it [24].

Furthermore, a multiresolution strategy for surface reconstruction of unstructured data was introduced in [98]. This method suggested the use of batch SOM, a set of mesh operators such as vertex removal, edge swap, triangle subdivision and vertex split, and simple constraints for selective mesh refinement to tackle the issue of SOM in reconstructing the surface at the concave regions of an object. This method can represent the surface of an
object with smaller number of triangles for the same resolution level compared to the surface reconstruction method proposed in [41]. It allows the user to set the threshold which controls the number of triangles in the meshes unlike the method proposed in [41] which subdivides every face in the mesh into four smaller faces at a certain resolution to get a higher resolution surface. In addition, a growing grid SOM with rectangular map was introduced in [32] to organise the unstructured data of open surfaces. The growing grid SOM can generate the open surfaces correctly. However, the map is not suitable to reconstruct the closed surface data and has the same problem as the 2-D SOM because the neurons at the edges of the maps are not connected to one another. The difference between them is that the grid size of the growing grid SOM increases from time to time but the grid size of the 2-D SOM remains the same throughout the learning process after initialisation.

Due to the fixed topology of SOM, the models based on SOM may generate a reconstructed surface with vertices or triangles dangling around the regions of dense data that does not belong to the original object [40]. Nevertheless, methods in [41], [102], [24], [40], [22] can be used to solve this problem. However, growing self-organising surface map [22] cannot generate the surface correctly if the point cloud is not uniformly-sampled and it requires some post-processing steps. In addition, a method in which the map can grow incrementally to produce meshes with various resolutions was introduced in [40] to solve this problem. The method can produce models that fit the shape of an object, including its concave regions and holes. However, this method may not preserve the topology of the map. The method will keep on changing,
inserting and removing the structural information of the map during the learning process.

Cube Kohonen SOM (CKSOM) [25] was introduced to address the holes problem of 2-D SOM in the reconstruction of closed surface and the connectivity problem of the 3-D SOM. The model was created through the merging of six 2-D SOMs. As shown in [25], the CKSOM model performs better than the 2-D SOM and 3-D SOM models and the model was also tested with different types of data sets. Despite its ability to deal with the problems of both 2-D and 3-D SOMs, it restricts the user to set different width and length of the grid. Hence, objects with longer widths or lengths may fail to reconstruct efficiently [25]. The model would use a larger grid size to reconstruct the objects. Furthermore, DL SOM [42] is also introduced to reconstruct the closed surface data. Although it could deal with closed surface, it failed to produce the correct connectivity for the concave area of the object. Therefore, DL SOM is not considered in this research.

Based on the previous works, SOM models were able to organise the unstructured data and generate the correct surface. However, previous works show that the SOM models are still suffering from limitation that needs to be addressed and the surface generated is not the standard representation in CAGD. Therefore, NURBS surface was often used to represent the output of the SOM models. Previous works [23], [28] have shown that the output of the SOM model with rectangular topology can be applied with NURBS surfaces. In addition. the NURBS surfaces can be optimised using optimisation
techniques to generate surface with higher accuracy. Hence, the optimisation techniques related to surface reconstruction are discussed in the next section.

### 2.5 Optimisation Techniques

Optimisation techniques such as Genetic Algorithm (GA), Differential Evolution (DE) and Particle Swarm Optimisation (PSO) are often implemented to optimise the free-form parametric curve and surface such as B-Spline and NURBS in surface reconstruction.

GA was proposed by John Holland based on the survival of the fittest and it is a population-based optimisation technique. GA has four main operators and selection, crossover, mutation and replacement. Each individual or chromosome is a single possible solution in GA and each individual and chromosome is subdivided into genes. Each gene is represented according to an encoding scheme and the encoding scheme is determined according to the optimisation problem.

Encoding is a process of representing the chromosomes [107]. Value encoding scheme is mainly used in neural networks to find their optimal weights as the chromosome is represented with string of values and the values can be real, integer number or character. Selection is performed after the chromosomes are encoded. Selection is a process of choosing two or more individuals to perform crossover and mutation. Tournament Selection is the most popular selection scheme in GA because it is easy to implement [108], [109]. However, the tournament size set for the Tournament Selection cannot be too large. When the tournament size is large, the probability of loss diversity is also greater [110]. The individual selected to perform crossover is
known as parent. Crossover operator is performed after the parents are selected with the selection operator. Crossover allows genes in the selected individuals to be exchanged to produce new solutions [111]. One of the common crossover schemes is Uniform Crossover. In Uniform Crossover, every gene is exchanged between the pair of randomly selected chromosomes with the swapping probability, $p_{e}$ and it is typically set to 0.5 [113]. The crossover operator is used to prevent the duplication of the parents from the old population in the offspring. After the offspring are generated by crossover, the mutation is performed on the offspring. The mutation operator helps to maintain the diversity of the population by introducing new elements into the chromosomes [114] and prevents the algorithm from being trapped in a local minimum [107]. One of the mutation operators is Uniform Mutation [115]. In Uniform Mutation, a predefined number of genes are selected randomly and each of the gene is assigned with a value that is randomly generated within a certain range. It is used in value encoded GA. The replacement operator is executed after the mutation operator. The replacement operator includes Weak-Parent Replacement [107]. In Weak-Parent Replacement, the parents with lower fitness value than the offspring are replaced with their offspring in the next generation. The GA continues with selection, crossover, mutation and replacement operators until a stopping criterion is achieved which can be the achievement of certain number of generation or certain fitness value in which the fitness value is calculated with a fitness function.

Two important parameters used in GA are crossover probability, $P_{c}$ and mutation probability, $P_{m} . P_{c}$ and $P_{m}$ are used to control the crossover and mutation respectively. $P_{c}$ is in the range of $[0,1]$ in which 0 indicates that the
completely new generation of individuals would be the same as the older population except those resulted from the mutation operator and 1 indicates that all the offspring are generated by crossover [112]. $P_{m}$ is set in the range of $[0,1]$. If the mutation probability is 1 , the whole chromosome is altered, otherwise nothing is altered. The mutation probability should not be set too high as it will change the GA into a random search [107].

Differential Evolution (DE) was a population-based optimisation technique proposed by Storn and Price [33] in 1997 and its main operations are initialisation, mutation, crossover and selection. During initialisation, a population of $N$ individuals are encoded as $D$-dimensional vectors of real numbers is generated and $D$ elements of each vector are randomly initialised within $\left[x_{\min }, x_{\max }\right]$ where $x_{\max }$ is the maximum value of the search space, $x_{\min }$ is the minimum value of the search space. The population with $N$ individuals can be expressed as $X=\left(x_{1}, x_{2}, \ldots, x_{N}\right)$. Each individual can be expressed as $x_{i}(t)=$ $\left(x_{i 1}(t), x_{i 2}(t), \ldots, x_{i D}(t)\right)$ where $x_{i}(t)$ is the $i$-th individual, $x_{i D}(t)$ is the $D$ elements of the $i$-th individual at $t$ and $t$ is the current generation. Each individual is the possible solution to the optimisation problem.

Mutation operation is performed after the initialisation of the individuals. In mutation operation, a mutant vector is generated with a mutation strategy for each target vector. A mutant vector in the original DE is generated by adding the weighted difference between two vectors to a third vector and it is represented as follows [29]:

$$
v_{i, G+1}=x_{r 1, G}+F\left(x_{r 2, G}-x_{r 3, G}\right)
$$

where $r_{1}, r_{2}, r_{3}$ are randomly chosen integers, mutually exclusive from one another and they are also different from the index $i$. Since $r_{1}, r_{2}, r_{3}$, and $i$ are distinct, $N$ must be greater or equal to four to abide this condition. $F$ is a scaling factor which controls the amplification of the differential variations $\left(x_{r 2, G}-x_{r 3, G}\right)$ and its value is within [0, 2].

The crossover was performed after the mutant vector was generated through the mutation strategy to increase the diversity of the population [116]. During the crossover, a trial vector $u_{j i, G+1}$ is developed from the elements of the target vector, $x_{i, G}$, and the elements of the mutant vector, $v_{i, G+1}$. Binomial crossover is the commonly-used crossover and it is defined as follow [117]:

$$
u_{j i, G+1}=\left\{\begin{array}{l}
v_{j i, G+1}  \tag{2.13}\\
\text { if } \operatorname{rand}_{j i} \leq C R \text { or } j=r n b r_{i} \\
x_{j i, G} \quad \text { if } \operatorname{rand}_{j i}>C R \text { and } j \neq r n b r_{i}
\end{array}, i=1,2, \ldots, N ; j=1,2, \ldots, D\right.
$$

where $\operatorname{rand}_{j i}$ is the uniform random number generator in the range $[0,1]$ for $j$ th dimension of the $i$-th individual, $C R$ is the predefined crossover probability, chosen from the range $[0,1]$, rnbr $_{i}$ is a randomly selected integer is an element of $1,2, \ldots, D$ and it is to ensure that $u_{i, G+1}$ has at least one parameter from $v_{i, G+1}$.

The fitness value of the trial vector is evaluated with a fitness function and the selection operation is performed after the crossover operation. In selection operation, the fitness value of the trial vector is compared with that of the target vector in the current population. If the fitness value of the trial vector is less than or equal to that of the target vector, the target vector is replaced by the trial vector in the next generation. Otherwise, the target vector is remained for the next generation. The selection operation described above can be expressed as follows [118]:

$$
x_{i, G+1}=\left\{\begin{array}{ll}
u_{i, G+1} & \text { if } f\left(u_{i, G+1}\right) \leq f\left(x_{i, G}\right)  \tag{2.14}\\
x_{i, G} & \text { otherwise }
\end{array} i=1,2, \ldots, N\right.
$$

where $x_{i, G}$ is the target vector of $i$-th individual, $u_{i, G+1}$ is the trial vector, $f\left(u_{i, G+1}\right)$ is the fitness value of the trial vector, $f\left(x_{i, G}\right)$ is the fitness value of the target vector, $N$ is the total number of individuals.

Particle Swarm Optimisation (PSO) was developed by Eberhart and Kennedy [119] in 1995 and it was inspired by the social behaviour of bird flocking and fish schooling in food searching [119]. Various variants of PSO were introduced to solve different kinds of optimisation problems. The original PSO was defined in Equation 2.18. Each particle has velocity and position. The position of each particle corresponds to a possible solution of the problem. The position of each particle is initialised randomly within the lower and upper bound of the optimisation problem. The Equations 2.15 and 2.16 are used to update the particles positions.

$$
\begin{gather*}
x_{i j}^{(t+1)}=x_{i j}^{(t)}+v_{i j}^{(t+1)}  \tag{2.15}\\
v_{i j}^{(t+1)}=v_{i j}^{(t)}+c_{1} r_{1}\left(x_{i j}^{p(t)}-x_{i j}^{(t)}\right)+c_{2} r_{2}\left(x_{j}^{g(t)}-x_{i j}^{(t)}\right) \tag{2.16}
\end{gather*}
$$

where $i$ is the number of particle, $t$ is the current generation, $x_{i j}$ and $v_{i j}$ are the $i$ th position and velocity of the particle in the $j$-th dimension, $c_{1}$ and $c_{2}$ are the cognitive and social acceleration constants respectively, $r_{1}$ and $r_{2}$ are the random number which are uniformly distributed between 0 and $1, x_{i j}^{p(t)}$ is the best previous position of particle $i$ in $j$-th dimension, $x_{j}^{g(t)}$ is the global best position in $j$-th dimension.

Other than the original PSO, various variants of PSO were introduced through the modification of Equation 2.16. One of the variants of PSO is the PSO with inertia weight and it is defined as follows:

$$
\begin{equation*}
v_{i j}^{(t+1)}=w v_{i j}^{(t)}+c_{1} r_{1}\left(x_{i j}^{p(t)}-x_{i j}^{(t)}\right)+c_{2} r_{2}\left(x_{j}^{g(t)}-x_{i j}^{(t)}\right) \tag{2.17}
\end{equation*}
$$

The inertia weight, $w$ is one of the PSO parameters originally proposed in [120] to balance the exploration and exploitation characteristics of PSO by controlling the velocity of the particles. Constant inertia weight within the range [0.9, 1.2] was preferred in [120]. Besides, PSO with constriction factor, $K$ is also another variant of PSO and it was introduced by [121] to analyse the convergence behaviour [122]. It can be incorporated by modifying the Equation 2.16 to Equation 2.18 [123].

$$
\begin{equation*}
v_{i j}^{(t+1)}=K\left[v_{i j}^{(t)}+c_{1} r_{1}\left(x_{i j}^{p(t)}-x_{i j}^{(t)}\right)+c_{2} r_{2}\left(x_{j}^{g(t)}-x_{i j}^{(t)}\right)\right] \tag{2.18}
\end{equation*}
$$

where

$$
\begin{equation*}
K=\frac{2}{\left|2-\rho-\sqrt{\rho^{2}-4 \rho}\right|} \text {, where } \rho=c_{1}+c_{2}, \rho>4 \tag{2.19}
\end{equation*}
$$

The constriction factor, $K$ is set to 0.729 based on Equation 2.20.

$$
\begin{equation*}
\rho=c_{1}+c_{2}=4.1 \tag{2.20}
\end{equation*}
$$

where $c_{1}$ and $c_{2}$ are both set to 2.05 .

Eberhart and Shi [123] compared the performance between the PSO with inertia weights and constriction factors and it was found that the performance of the PSO with constriction factor and velocity clamping is on par with the PSO with inertia weights. Velocity clamping was introduced to control the global exploration of the particle by keeping the particles within the search space [124].

GA, DE and PSO were applied in the optimisation of parametric curves and surfaces. In 2007, GA was applied in [78] to perform Bézier curve
and surface parameterisation. Furthermore, GA is applied in [125] to fit the data points with B-Spline surface. GA was first used to find the parameter values of the data points. Then the GA was applied again to find the knot vectors. In addition, DE is also another optimisation method that are being applied widely to optimise the parametric curves and surfaces. DE was applied in [29] to find the optimised control points of the Bézier curve. DE was applied to optimise the control points of the NURBS surfaces in [28]. Besides, PSO was applied to obtain a suitable parameterisation of the data points for Bézier surface reconstruction in [31]. PSO was applied to determine the optimal location of knots in B-Spline curve [80]. PSO was used in the surface fitting of NURBS to obtain the control points and their weights, parametric values of the data points and knot vectors without any pre- or post-processing [30]. Hence, GA, DE and PSO can be applied in solving surface reconstruction case studies.

### 2.6 Summary

Based on the discussions in the previous sections, it is noticed that the process in surface reconstruction begins with the acquisition of the data in which the data can be in the form of structured or unstructured and ends with the generation of a surface that represent the data. When the data is in unstructured form, reorganisation of the data is required to regain the connectivity information among the data so that the original shape of the object can be recovered. Reorganisation of the data can be performed with self-organising map (SOM) models. However, the models have their own limitations.

It is also noticed that the explicit surface tends to represent the data incorrectly when the data has noise. In addition, the implicit surface tends to overfit the data and the deep learning methods are also suffering with limitation such as fails to generate the correct surface. Parametric surface is commonly-used in the real-world applications due to its flexibility and ability to represent the shape of an object well. It is discovered that the output of the SOM model can be represented with the parametric surface and this would make the SOM model to be useful in the field of computer aided geometric design (CAGD). Although the parametric surface can be used to represent the output of the SOM model using the mathematical formula, the accuracy of the parametric surface is not optimal because it is generated with control points, weights, parameters or knot vectors that are not optimal. To overcome the problem, the free-form parametric surfaces can be optimised with GA, DE and PSO either through the optimisation of control points, weights, parameters and knot vectors.

## CHAPTER 3

## RESEARCH METHODOLOGY

### 3.1 Overview

This chapter discusses the methodology of the research and provides a general flow of the research beginning with the literature review and problem definition, data collection and definition, organise the unstructured data using Double Net Self-Organising Map (DNSOM) model, integrate the improved NURBS surface approximation approach on the DNSOM model, optimise the improved NURBS surface approximation approach with optimisation techniques, and documentation.

### 3.2 Research Framework

This section discusses the research framework and provide a general information about the tasks involved in this research. Figure 3.1 illustrates the research framework of this research.

### 3.2.1 Literature Review and Problem Definition

Initially, a thorough literature review was conducted to gain a good understanding on the existing research and to identify the unexplored areas related to the research title. Literature review also helps to build the knowledge on the research title. The theories, concepts and previous works of SOM, free-form parametric curves and surfaces such as B-Spline and NURBS, and optimisation techniques such as Genetic Algorithm (GA), Differential Evolution (DE) and Particle Swarm Optimisation (PSO) related to surface reconstruction were studied. The problem statement of this research was
defined based on the findings of the literature review. Upon the definition of the problem statement, three objectives were determined to overcome the defined problems.

Figure 3.1: Research Framework

### 3.2.2 Data Collection and Definition

After performing a thorough literature review, identifying the problem and determining the objectives of the research, data collection was performed. The data required are collected and their properties were defined. For the data to be applicable in this research, the data collected must be in coordinate ( $x, y, z$ ) and unstructured form. The data collected includes four primitive shapes [25] and a medical data [45]. The four primitive shapes were the cube, sphere, spindle and oiltank data, and the medical data was the talus bone data. The general information about the data and the visualisation of the data were provided in Table 3.1 and Table 3.2 respectively. The cube, sphere, spindle, oiltank and talus bone have $7352,7082,7552,5942$ and 5253 data points respectively. The data were visualised with GNUPlot and they were demonstrated in Table 3.1. The data show that they are in unstructured form. The data were normalised and the first five coordinates of each data were included in Table 3.1. Figure 3.2 is the superior view of the talus bone and it was adapted from [126]. The figure was included to demonstrate the structure of the talus bone. Additional data which is the Stanford bunny data with 35947 data points were used to test the performance of the DNSOM model and the visualisation of the data was shown in Table 3.2.

### 3.2.3 Organise the Unstructured Data using the DNSOM Model

Organise the unstructured data using the DNSOM model was the first objective of this research. The motivation of this objective was to develop a model using two 2-D Self-Organising Map (SOM) to form the DNSOM model in which the model was able to overcome the limitation of the 2-D SOM and 3-D SOM in organising the unstructured data. At the same time, the model
was able to organise the unstructured data with fewer number of neurons compared to the Cube Kohonen SOM (CKSOM) model proposed in [25]. This was achievable because only two 2-D SOMs were used to develop the DNSOM model and the model allows the setting of different grid size. Data reduction is one of the important properties of the SOM.

Table 3.1: Data information

| Data | No. of data points | $x$ | $y$ | $z$ |

Figure 3.2: Superior view of talus bone. Adapted from [126]

Five performance measurements were used to compare the performance among the models, which are minimum and maximum error, Quantisation Error (QE), Topographic Error (TE) and CPU time. Minimum error, maximum error and CPU time were recommended in [25]. Meanwhile, the QE was applied in [25], [127]. The TE was used in [127]. The output of the DNSOM model was structured and it is known as the DNSOM surfaces data. The output of the model was used as the input of the second objective.

### 3.2.4 Integrate the Improved NURBS Surface Approximation Approach on the DNSOM Model

Integrate the DNSOM model with improved NURBS surface approximation approach is the second objective of this research. The output of the DNSOM model was used as the input of this objective and they include the output of the model for the cube, sphere, talus bone, oiltank and spindle data. All outputs were structured 3-D data points. Although the data are structured, it is not the standard representation in Computer-Aided Geometry Design (CAGD) industries [23]. Therefore, the model cannot be applied in CAGD directly. To overcome this challenge, free-form parametric surfaces such as NURBS are used to represent the output of a model and they are the common standard
representation in CAGD. Hence, NURBS surfaces were used to represent the DNSOM surface data. The conventional NURBS surface approximation approach from [23] was applied on each 2-D SOM separately with different parameterisation methods and sizes of control net (CN). Consequently, the NURBS surfaces were generated. Besides, improvements were made to the conventional NURBS surface approximation approach and it is known as improved NURBS surface approximation approach. The improved approach was applied on all the output of the model with different parameterisation methods and sizes of CN. The performance measurement involved in this objective is known as surface error and it was derived based on the DNSOM model and Euclidean distance. The outputs of both approaches for each of the data include the basis function, NURBS surfaces data and surface error.

### 3.2.5 Optimisation on the Improved NURBS Surface Approximation Approach

Optimisation techniques were proposed to optimise the improved NURBS surface approximation approach aiming to achieve smaller surface error between the improved NURBS surface data and the DNSOM surface data, which is the third objective of this research. It can be achieved by optimising the control points of the improved approach. The quantitative and qualitative performance measurement used in this objective were optimised surface error between the optimised improved NURBS surfaces data and the DNSOM surface data, and visualisation respectively. The surface error was utilised to evaluate the performance between the optimisation techniques and it was computed based on Euclidean distance and the DNSOM surface data. Besides, visualisation was used to evaluate and to compare the optimised improved

NURBS surfaces with the improved NURBS surfaces from the second objective, aiming to identify the differences between the improved NURBS surfaces before and after optimisation. The inputs for this objective include the DNSOM surface data, the basis functions, control points and NURBS surface data of the improved NURBS surface approximation approach. Each of the optimisation technique was applied on various parameterisation methods, sizes of CN and data. The outputs of this objective were the optimised control points, optimised surface error, CPU time and optimised improved NURBS surfaces data.

### 3.2.6 Documentation

Documentation is the final and important step in this research. The system flow of each objective was documented accordingly alongside with their outcomes and findings.

### 3.3 Hardware and Software Requirements

The hardware used in this research is a desktop with Intel $\circledR^{\circledR}$ Core ${ }^{\text {TM }}$ i7-7700K CPU @ 4.20GHz, NVIDIA GeForce GTX 1050 2GB and 32 GB RAM. Meanwhile, the software used in this research were Microsoft Visual Studio 2022 with C++ programming and GNUPlot. Microsoft Visual Studio 2022 with $\mathrm{C}++$ programming was used to code the models in first objective, the surface approximation approaches in second objective and the optimisation techniques in the third objective, and to perform every experiment in this research. Besides, visualisation was conducted with GNUPlot.

### 3.4 Summary

The theories and concepts of SOM models, B-Spline and NURBS curves and surfaces as well as GA, DE and PSO were studied when conducting the literature review. After conducting the literature review, it was noticed that the 2-D SOM, 3-D SOM and CKSOM models are still suffering from limitation and the output of the models are not a standard representation in CAGD. The output of the model can be represented with NURBS surfaces but gaps were identified when the output of the model were represented with the NURBS surfaces separately. Additionally, the NURBS surfaces generated may not have a high accuracy. After defining the problems, data were collected and defined. The data collected were in coordinates $(x, y, z)$ and unstructured form. The unstructured data were organised with the DNSOM model. The improved NURBS surface approximation approach was applied on the output of the DNSOM model to generate the NURBS surfaces without gaps and optimisation techniques were used to optimise the improved NURBS surfaces. Lastly, the system flow, findings and discussions involved were documented.

## CHAPTER 4

## THE DOUBLE NET SELF-ORGANISING MAP (DNSOM) MODEL

### 4.1 Overview

As mentioned before, 2-D SOM model has holes problem, 3-D SOM model has connectivity problem and CKSOM model has problem settings its grid size with different length and width. Hence, this chapter proposes a model to organise the unstructured data and addresses the limitations of the models. The model was formed through the merging of two 2-D SOMs and it was inspired by Lim and Haron [25]. The proposed model is known as Double Net SelfOrganising Map (DNSOM). Acquiring Data, Initialising Parameters, Merging Neurons, Detecting Neighbours, Generating Weights, Learning Process and Producing Output are the processes involved in organising the unstructured data with the model. Class Number was used to group the neurons on the border of two views in DNSOM model during Merging Neurons and this would solve the issues of holes because neurons grouped in the same class number were assigned with the same weight vector to perform the learning process. The neuron with the same class number will be updated if it was selected as the winning or neighbouring neurons during the learning process. This chapter also presents the performance of the DNSOM model.

### 4.2 System Flow of the DNSOM Model

Figure 4.1 shows the steps included in the DNSOM model to overcome the holes problem in 2-D SOM, the connectivity problem in 3-D SOM and the inability to set different grid size in Cube Kohonen SOM (CKSOM). The
model was inspired based on the work of Lim and Haron [25] and it was proposed to organise the unstructured data. Three new equations were derived to construct the model.

Figure 4.1: Flowchart of the DNSOM model

### 4.2.1 Acquiring Data

The data applied in this research were described in Research Methodology (Chapter 3) and they include four sets of primitive data (cube, sphere, spindle and oiltank), one set of medical image data (talus bone) and a complex data (Stanford bunny). Generally, all the data are in 3-D coordinates ( $x, y, z$ ) and unstructured form. The data were inserted into the DNSOM model and they were randomly chosen as the input vector of the DNSOM model in Learning Process (Section 4.1.6).

### 4.2.2 Initialising Parameters

Table 4.1 shows the parameters initialised for the DNSOM model and they were referred from [25], [98]. The same values of parameters in Table 4.1 were initialised for the 2-D SOM, 3-D SOM and CKSOM models for comparison purposes. Rectangular topology was used for the DNSOM model because the NURBS surfaces uses such topology as input data [77]. Every neuron in the model has a weight vector in which its dimension is identical to that of the input vector or data. Since the data are in 3-D, the dimension of the weight vector was set to 3 . Furthermore, this step includes the initialisation of grid size, $n$, initial learning rate, $\alpha_{0}$, initial radius, $\sigma_{0}$ and maximum iterations, $T$ for the model. The time constant, $\tau$ was also calculated in this step. The learning rate was used to control the weight of the neurons during the Learning Process (Section 4.2.6) [128] and the initial learning rate was referred from [25]. The radius was used to determine the neighbourhood distance for each winning neuron. The initial radius was set to half of the $n$ and it was referred from [25]. The learning rate and radius would eventually reduce to 0.01 and 1 during the learning process [25]. Maximum iteration, $T$
was the total number of iterations for the model in learning towards the input vector [25]. The time constant, $\tau$ was applied to handle the decay rate of the learning rate and the radius. Its value was derived with the maximum iterations and the logarithm of initial radius, $\log \left(\sigma_{0}\right)$, and it was recommended by [98]. The value of $n$ was assigned to the width, $n_{x}$ and length, $n_{y}$ of the grid for the DNSOM model. When different values of $n_{x}$ and $n_{y}$ were used to set the grid size, the initial radius was set to the half of the minimum value between $n_{x}$ and $n_{y}$ and it was proposed in [129].

Table 4.1: Parameters and their respective values

| Parameter | Value |
| :--- | :--- |
| Dimension of weight vector | 3 |
| Grid size, $n$ | $10,20,30$ |
| Initial Learning Rate, $\alpha_{0}$ | 0.9 |
| Initial Radius, $\sigma_{0}$ | Half of the grid size |
| Maximum iteration, $T$ | 30000 |
| Time constant, $\tau$ | Derived with Maximum iteration and the <br> Logarithm of the Initial Radius |

As mentioned in [25], Index Vector was assigned to each neuron to form the structure of the CKSOM model and to identify the neighbours for each neuron. It was adapted in this research to form the structure of the DNSOM model. The Index Vector consists of three index values ( $i, j$ and $k$ ). The index values, $i$ and $j$, start with 0 and increase by 1 until $n_{x}-1$ and $n_{y}-1$ respectively. Similar to CKSOM model, Index Vector was set from bottom to top and left to right. $k$ for neurons with $i=0, i=n_{x}-1, j=0$ and $j=n_{y}-1$ was set to 1 as $k=1$ refers to neurons in both maps that are merged to create a connection between the two maps. The $k$ of the remaining bottom and top neurons was set to 0 and 2 respectively and $k=0$ refers to the neurons at the
bottom view while $k=2$ refers to the neurons at the top view. This is to indicate the neurons that are not merged while forming the structure of the DNSOM model and to create a space between the two views for organising the closed surface data. Figure 4.2 shows an example the Index Vectors allocated for the bottom view with the grid size of $n_{x}=4$ and $n_{y}=5$. The bottom and top views were referred to the two 2-D SOMs.

Figure 4.2: Allocation of Index Vectors for the bottom view with grid size,

$$
n_{x}=4 \text { and } n_{y}=5
$$

### 4.2.3 Merging Neurons

Two 2-D SOMs were merged in Merging Neurons (Section 4.2.3) to overcome the issues of 2-D SOM and 3-D SOM models. However, neurons with the same Index Vector would cause redundancy problem during learning process after SOMs were merged. Hence, Class Number was used to group the same neurons and update the weight of the neurons to overcome the redundancy problem. The grid size of the DNSOM model is determined with two parameters which are the width, $n_{x}$ and length, $n_{y}$. Due to different grid sizes, three new equations were derived in this research. Equation 4.1 was formed to compute the total number of neurons (NON) of the DNSOM model.

$$
\begin{equation*}
\mathrm{NON}=2 n_{x} n_{y} \tag{4.1}
\end{equation*}
$$

Equation 4.2 was formed to compute the total number of output neurons (NOV) involved in the learning process.

$$
\begin{equation*}
\mathrm{NOV}=2\left[n_{x} n_{y}-n_{x}-n_{y}+2\right] \tag{4.2}
\end{equation*}
$$

The NOV represents the total number of Class Number allocated to group the neurons with similar Index Vector together. It also refers to the number of vertices used to represent the surface of the data. Equation 4.3 was formed to compute the total number of redundancies (NOR) for any grid size.

$$
\begin{gather*}
\mathrm{NOR}=2 n_{x}+2\left(n_{y}-2\right) \\
\text { or } \\
\mathrm{NOR}=2 n_{y}+2\left(n_{x}-2\right)  \tag{4.3}\\
\text { or } \\
\text { NOR }=\text { NON }- \text { NOV }
\end{gather*}
$$

Neurons from the bottom and top views with the same Index Vector were grouped with the same Class Number. The allocation of Class Number based on the Index Vector of each neuron for the DNSOM model with the grid size, $n_{x}=4$ and $n_{y}=5$ and NON $=40$ was tabulated in Table 4.2.

Figure 4.3 shows the bottom and top view of the DNSOM model using the Class Number to represent the position of the neurons and the allocation of Class Number in the DNSOM model starts with the bottom view, followed by the top view. Each of the Class Number was allocated sequentially from the bottom to top and left to right. Figure 4.4 shows the bottom and top views of the model in Figure 4.3. Figure 4.5 shows the DNSOM model with the grid size, $n_{x}=4$ and $n_{y}=5$.

Figure 4.3: Bottom and top views of the DNSOM model with Class
Number for grid size, $n_{x}=4$ and $n_{y}=5$

After the process was completed, the Class Numbers and their respective Index Vector were extracted as shown in Table 4.3. Based on the
information in Table 4.3, 26 neurons were used in the Learning Process (Section 4.2.6) and they represent the output layer of the model. Nevertheless, all the 40 neurons were used for the Producing Output (Section 4.2.7).

Figure 4.4: Bottom and top views of the DNSOM model with grid size, $n_{x}$

$$
=4 \text { and } n_{y}=5
$$

Figure 4.5: The DNSOM model with grid size, $\boldsymbol{n}_{x}=4$ and $\boldsymbol{n}_{\boldsymbol{y}}=5$ after merging both views from Figure 4.4

### 4.2.4 Detecting Neighbours

Detecting Neighbours determines the neighbours for each Class Number. Redundant neurons were grouped and represented with a Class Number after Merging Neurons (Section 4.2.3). Due to the use of Class Number to represent the structure of the DNSOM model, the model would have different neighbourhood from the 2-D SOM model. Index Vector was used to identify the neighbouring neurons of each Class Number.

Table 4.3: Extracted Class Number with Index Vector

| Class Number | Index Vector |  |  | Class <br> Number | Index Vector |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $i$ | $j$ | $k$ |  | $i$ | $j$ | $k$ |
| 1 | 0 | 0 | 1 | 14 | 2 | 3 | 0 |
| 2 | 0 | 1 | 1 | 15 | 2 | 4 | 1 |
| 3 | 0 | 2 | 1 | 16 | 3 | 0 | 1 |
| 4 | 0 | 3 | 1 | 17 | 3 | 1 | 1 |
| 5 | 0 | 4 | 1 | 18 | 3 | 2 | 1 |
| 6 | 1 | 0 | 1 | 19 | 3 | 3 | 1 |
| 7 | 1 | 1 | 0 | 20 | 3 | 4 | 1 |
| 8 | 1 | 2 | 0 | 21 | 1 | 1 | 2 |
| 9 | 1 | 3 | 0 | 22 | 1 | 2 | 2 |
| 10 | 1 | 4 | 1 | 23 | 1 | 3 | 2 |
| 11 | 2 | 0 | 1 | 24 | 2 | 1 | 2 |
| 12 | 2 | 1 | 0 | 25 | 2 | 2 | 2 |
| 13 | 2 | 2 | 0 | 26 | 2 | 3 | 2 |

Equation 4.4 - 14 were used to detect the neighbouring neurons and they are referred from [25], [93], [98].

$$
\begin{align*}
I & =\left|i_{\mathrm{WCN}}-i_{\mathrm{NCN}}\right|  \tag{4.4}\\
J & =\left|j_{\mathrm{WCN}}-j_{\mathrm{NCN}}\right|  \tag{4.5}\\
K & =\left|k_{\mathrm{WCN}}-k_{\mathrm{NCN}}\right|  \tag{4.6}\\
\text { dist }^{2} & =\left(\sqrt{I^{2}+J^{2}+K^{2}}\right)^{2}  \tag{4.7}\\
\text { dist } & =\sqrt{I^{2}+J^{2}+K^{2}} \tag{4.8}
\end{align*}
$$

where $i_{\mathrm{WCN}}, j_{\mathrm{WCN}}$ and $k_{\mathrm{WCN}}$ are the Index Vector of the winning neuron, $i_{\mathrm{NCN}}$, $j_{\mathrm{NCN}}$ and $k_{\mathrm{NCN}}$ are the Index Vector of the neighbouring neuron, $I, J$ and $K$ are the distance of index $i, j$ and $k$ between the winning neuron and the neighbouring neuron, dist $^{2}$ is the distance used in the learning process of SOM, dist is the Euclidean distance between the winning neuron and neighbouring neuron computed using their respective Index Vector.

Additional condition was added to determine the neighbours of each Class Number. After the winning neuron was identified, the distance between the winning neuron and a neighbouring neuron was computed with Equation 4.8. The weight of the neighbouring neuron was updated if the dist for the neuron is smaller than the radius decay and its value of $K$ is not equal to 2 and the value of the dist ${ }^{2}$ was substituted into Equation 4.11, Section 4.2.6 for that specific neuron. Neighbouring neuron with dist smaller than the radius decay indicates that the neurons is a valid neighbour of the winning neuron since it is inside the neighbourhood radius of the winning neuron [93]. Meanwhile, the valid neighbouring neuron of the winning neuron must have the value of $K$ not equal to 2 in order to update its weight. This is to ensure that the neighbouring neuron is not located at the opposite view. If the weight of the neurons located at opposite view of the winning neuron was updated, the surface generated will contain gaps. Table 4.4 shows an example of a winning neuron, Class Number 7 was used to calculate its distances to each Class Number using Equations $4.4-4.7$. When the Class Number 7 is selected as the winning neuron, the weight of the neighbouring neurons with Class Number $21-26$ will not be updated although the dist for the neurons is smaller than the radius decay because the value of $K$ is equal to 2 . This condition is applied to avoid the weight of the neurons from the top view to be updated when the winning neuron is from the bottom view. Conversely, when the winning neuron is from the top view, the weights of the neurons from the bottom view will not be updated. With this condition, the correct surface can be generated.

Table 4.4: Distances between Class Number 7 and each Class Number

| Class <br> Number | Class Number 7 |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | $J$ | $K$ |
|  |  |  |  |  |
| 1 | 1 | 1 | 1 | 3 |
| 2 | 1 | 0 | 1 | 2 |
| 3 | 1 | 1 | 1 | 3 |
| 4 | 1 | 2 | 1 | 6 |

| 26 | 1 | 2 | 2 | 9 |

### 4.2.5 Generating Weights

Weights for each neuron, $W$, were generated with the random values ranging from 0 to 1 . Same weights were assigned to the neurons with the same Class Number. The neurons represent the vertices of the model and the Index Vector represents the position of each the neurons. Meanwhile, the weights were depicted as 3-D coordinates $(x, y, z)$. The weights were utilised to fit the input vector and produce the final output after the Learning Process (Section 4.2.6).

### 4.2.6 Learning Process

Learning process begins after the generation of weights and completes with the production of output. Figure 4.6 shows a flowchart summarising the learning process.

Figure 4.6: Learning Process flowchart

The phases included in the learning process are competition, cooperation and adaptation. One input vector $X$ was chosen randomly from the data at the competition phase. The neuron with the least Euclidean distance to
$X$ was chosen as the winning neuron and the Euclidean distance was calculated with Equation 4.9.

$$
\begin{equation*}
d_{j}=\sqrt{\sum_{i=0}^{i=2}\left(X_{i}(t)-W_{i j}(t)\right)^{2}} \tag{4.9}
\end{equation*}
$$

where $W_{i j}$ is the weight connecting the $i$ th element in the input vector and $j$ th neuron, $X_{i}$ is the input vector, $d_{j}$ is the Euclidean distance and $t$ is the iteration. The weights of the winning neuron and its neighbouring neurons were updated with the Gaussian function (Equations $4.10-4.14$ ) at the cooperation and adaptation phases.

$$
\begin{gather*}
W(t+1)=W(t)+G_{f}(X(t)-W(t))  \tag{4.10}\\
G_{f}=\alpha(t) \exp \left(-\frac{\operatorname{dist}^{2}}{2 \sigma^{2}(t)}\right), t=1,2,3, \cdots, T  \tag{4.11}\\
\alpha(t)=\alpha_{0} \exp \left(-\frac{t}{\tau}\right), t=1,2,3, \cdots, T  \tag{4.12}\\
\sigma(t)=\sigma_{0} \exp \left(-\frac{t}{\tau}\right), t=1,2,3, \cdots, T  \tag{4.13}\\
\tau=\frac{T}{\log \left(\sigma_{0}\right)} \tag{4.14}
\end{gather*}
$$

where $W$ is the neuron weights, $X$ is the input vector, $G_{f}$ is the Gaussian function, dist $^{2}$ is the distance between winning neuron and the neighbouring neuron defined in Equation 4.7, $\alpha$ is the learning rate at $t$ iteration, $\alpha_{0}$ is the initial radius, $T$ is the total number of iterations, $t$ is the current iteration, and $\tau$ is the time constant.

When the weight of a neurons was updated, the weight of the neurons with the same Class Number was assigned with the same weight. However,
the dist for the neuron must be smaller than the radius decay or the neighbourhood radius of the winning neurons at $t$ iteration, and the value of $K$ is not equal to 2 in order to update its weight. The first condition was applied in the learning process of SOM to filter the invalid neighbouring neurons and to find the neighbouring neurons of the winning neuron [93]. Invalid neighbouring neurons are neurons having larger dist than the radius decay. The weight of the invalid neighbouring neurons would not be updated since they were outside the radius of the winning neuron. Generally, the weight of the valid neighbouring neurons was updated once the condition was fulfilled since they fall inside the neighbourhood radius of the winning neuron [93]. But the condition was insufficient to update the weight of the valid neighbouring neurons in the DNSOM model. The second condition was applied uniquely in the DNSOM model to prevent the weight of the neurons from the top view to be updated when a neuron from the bottom view was chosen as the winning neurons or vice versa. This is to prevent the neurons from the top view from learning towards the winning neuron of the bottom view or vice versa. The surface generated would be incorrect if the second condition is not applied. The learning process terminated when the maximum iteration was achieved. Then the process was continued with Producing Output (Section 4.2.7).

### 4.2.7 Producing Output

The final output was generated after the Learning Process (Section 4.2.6) was completed. The final output of the DNSOM model is 3-D structured data and it was the weight of every neuron $(x, y, z)$ which was outputted based on the Class Number.

### 4.3 Analysis and Discussion

This section analyses and discusses the performance between the 2-D SOM, 3D SOM, CKSOM and the DNSOM models based on the results obtained.

Table 4.5 shows the minimum and maximum Euclidean distance for the spindle data and SOM models. Table 4.6 shows the Quantisation Error (QE) and Topographic Error (TE) for the spindle data and SOM models. Meanwhile, Table 4.7 shows the CPU time for spindle data and SOM models. Table 4.8 shows the visualisation for spindle data and SOM models. The evaluation metrics and visualisation for the remaining data and SOM models were included in Appendix A and Appendix B respectively.

Table 4.5: Minimum and maximum Euclidean distance for spindle data and SOM models

|  |  |  |  |  |

Five evaluation metrics such as minimum and maximum errors, QE, TE and CPU time were used to measure the performance of the SOM models. The QE is an evaluation metric utilised to evaluate the accuracy of the SOM models and it was applied in [25], [130]. QE measures the average distance between the winning neuron and the input vector [131]. As for the TE, it is used to measure how good the structure of the inputs is modelled by the model [95]. This metric was used in [95], [131]. QE and TE are derived in Equation 4.15 and Equation 4.16:

$$
\begin{equation*}
Q E=\frac{1}{T} \sum_{t=1}^{T}\left\|X(t)-W_{c}(t)\right\| \tag{4.15}
\end{equation*}
$$

where $X(t)$ is the input data at the iteration $t, W_{c}(t)$ is the winning neuron's weight vector of input data $X(t)$ and $T$ is the maximum number of iterations.

$$
\begin{equation*}
T E=\frac{1}{T} \sum_{t=1}^{T} d(X(t)) \tag{4.16}
\end{equation*}
$$

where $X(t)$ is the input data at iteration $t$, if the first winning neuron and the second winning neuron of $x(t)$ is not adjacent, $d(X(t))=1$ and vice versa, $d(X(t))=0, T$ is maximum number of iterations.

Besides, CPU time is used to demonstrate the speed of the models in generating the output and it was suggested in [25]. Meanwhile, visualisation was used to visualise the surface of the models and it was also utilised in [25]. Table 4.9 shows the number of neurons involved in every SOM model and the total number of neurons or vertices used to represent the surface for the respective models and the grid sizes are highlighted in bold.

Table 4.9: Total output neurons representing the surface

| Grid <br> Size, <br> $n$ | 2-D <br> SOM | 3-D SOM | CKSOM |  |  | DNSOM |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $n \times n$ | $n \times n \times n$ | NON | NOR | NOV | NON | NOR | NOV |
| 10 | $\mathbf{1 0 0}$ | $\mathbf{1 0 0 0}$ | 600 | 112 | $\mathbf{4 8 8}$ | 200 | 36 | $\mathbf{1 6 4}$ |
| 20 | $\mathbf{4 0 0}$ | $\mathbf{8 0 0 0}$ | 2400 | 232 | $\mathbf{2 1 6 8}$ | 800 | 76 | $\mathbf{7 2 4}$ |
| 30 | $\mathbf{9 0 0}$ | $\mathbf{2 7 0 0 0}$ | 5400 | 352 | $\mathbf{5 0 4 8}$ | 1800 | 116 | $\mathbf{1 6 8 4}$ |

The minimum errors in Table 4.5 decrease when the grid size increases shows that the winning neurons can move closer towards the input data. As shown from the results in Table 4.6 and Table 4.7, the QE was reduced and the CPU time increased for every data set when the grid size was increased. The findings are aligned with the findings in [25]. Furthermore, the TE of the model decreases as the grid size increases. The higher the TE, the weaker the model in preserving the topology of the data. Besides, more vertices were used to represent the surface when the grid size increased. When the number of vertices representing the surface increases, the surface becomes smoother.

According to Table 4.6 and Table 4.7, 2-D SOM model had the highest QE and shortest CPU time. The high QE value shows that it had a low accuracy as the winning neuron is less fitted towards the input vector. The 2-D SOM model obtained the shortest CPU time because it used the least number of vertices to represent the surface as shown in Table 4.7 and Table 4.9. The model used the least number of vertices to represent the surface because it is a single map unlike the 3-D SOM, CKSOM models and the DNSOM model which are made up of $n$, six and two 2-D SOMs respectively and each of the map has the identical grid size of $n \times n$. Despite the ability of the 2-D SOM model to generate the outputs faster, it failed to reconstruct the surface of the closed surface data due to the absence of connectivity information between the neurons at the boundary [25], [42], [43] and the surface generated still contains holes as marked by the square in Figure 4.7. Thus, the 2-D SOM is the most underperforming SOM model when compared to others.

Figure 4.7: Visualisation for the 2-D SOM model with grid size, $\boldsymbol{n}=\mathbf{3 0}$ and spindle data retrieved from Appendix $B$. The surface generated contains holes as marked by the square.

As for the 3-D SOM model, it had the lowest QE, highest TE and CPU time. As shown in Table 4.9, the 3-D SOM model used the highest number of vertices to represent the surface. This is because it used $n \times n \times n$ neurons to represent the surface unlike the CKSOM model and the DNSOM model. The CKSOM model and the DNSOM model used six and two $n \times n 2$-D SOMs for their structure respectively and not all the neurons were used to represent the surface for both models. Meanwhile, they used the Class Number where only the distinct neurons the Class Number where only the distinct neurons were used to represent the surface. Therefore, the 3-D SOM model represented the surface with the greatest number of vertices. In addition, the model took the longest time to generate the output because there were more neurons involved in the training process. As marked by the circle in Figure 4.8 , the output of the model remained in unstructured form and incorrect surface was produced because the weights of both the internal neurons were updated during the learning process. Thus, the 3-D SOM model is not suitable for the surface reconstruction of closed surface data.

Figure 4.8: Visualisation for the 3-D SOM model with grid size, $\boldsymbol{n}=10$ and spindle data retrieved from Appendix $B$. The surface generated contains internal neurons as marked by the circle.

As for the CKSOM model, it had a lower QE compared to the 2-D SOM model, a slightly higher QE compared to the 3-D SOM model and a moderate CPU time. The CKSOM model had a higher accuracy than the 2-D SOM model as it had a lower QE compared to the 2-D SOM model. But it had a lower accuracy than the 3-D SOM model because it had a slightly higher QE compared to the 3-D SOM model. Although the CKSOM model achieved a lower accuracy than the model, it can generate the correct surface as shown in Table 4.8. Hence, the CKSOM model can reconstruct the surface of the closed surface data without holes and without connectivity problem between its neurons which eventually solves the problem of 2-D SOM and 3-D SOM models respectively. However, the model fails to organise the unstructured data and generate the correct surface with different grid sizes because the length and width of its grid are set with the same fixed value, $n$. The discussion can be referred to the additional experiment for CKSOM model with different grid size using the same data set. Furthermore, the results tabulated in Table 4.9 show that the CKSOM model used fewer number of vertices than 3-D SOM model to represent the surface.

As for the DNSOM model, it achieved the lowest TE among the models for all the data and grid sizes. This shows that the DNSOM model can preserve the topology of the data better than the other models. The results presented in Table 4.9 show that the DNSOM model used fewer number of vertices to represent the surface compared to the 3-D SOM and CKSOM models because it uses only two 2-D SOMs as compared to others. Additionally, it could generate output faster than 3-D SOM and CKSOM models since the number of neurons involved in the learning process was
fewer than the models. Similar to the CKSOM model, the DNSOM model can solve the problem of 2-D SOM and 3-D SOM models. It can represent the surface without holes and without any connectivity problem among the neurons as shown in Table 4.8. Besides, the DNSOM model was able to organise the unstructured data and generate the correct surface with different grid sizes.

Additional experiment was performed on the CKSOM and DNSOM models to examine their performance. Table 4.10 and Table 4.11 show the metric evaluation of the CKSOM and DNSOM models when different grid sizes were used given the spindle data. The metric evaluation for CKSOM and DNSOM models for the remaining data sets can be found in Appendix C. In contrast, Table 4.12 shows the visualisation of the CKSOM and DNSOM models when different grid sizes were used given the spindle data. The visualisation of CKSOM and DNSOM models for the remaining data sets can be found in Appendix D.

Table 4.10: Minimum and maximum Euclidean distance of CKSOM and DNSOM models with various sizes of width and length of grid given the spindle data

| $n_{x}$ | $n_{y}$ | Min Error |  | Max Error |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | CKSOM | DNSOM | CKSOM | DNSOM |

| 10 | 8 | 0.068216 | 0.103635 | 0.354700 | 0.239133 | 1.807986 | 0.428606 |
| 20 | 12 | 0.043618 | 0.063878 | 0.350600 | 0.227667 | 5.579232 | 1.391338 |
| 18 | 30 | 0.034528 | 0.048394 | 0.350400 | 0.222067 | 13.621258 | 3.096171 |

Table 4.12: Visualisation of CKSOM and DNSOM model for spindle data with different width and length of grid

| Data | CKSOM | DNSOM |
| :---: | :---: | :---: |
| $10 \times 8$ |  |  |
| $20 \times 12$ |  |  |
| $18 \times 30$ |  |  |

The DNSOM model was applied on the primitive and medical image data using $10 \times 8,20 \times 12$ and $18 \times 30$ grid sizes respectively. Besides, Table 4.13 shows the total number of output neurons used to represent the surface for
both CKSOM and DNSOM models given different $n_{x}$ and $n_{y}$. According to the results in Table 4.10 and Table 4.11, the findings of the CKSOM and DNSOM models are aligned to the findings of the models with the same grid size. Therefore, both models contain the same performance although different grid size was applied.

Table 4.13: Total output neurons of the CKSOM and DNSOM model
representing the surface for various $n_{x}$ and $n_{y}$

| $\boldsymbol{n}_{\boldsymbol{x}}$ | $\boldsymbol{n}_{\boldsymbol{y}}$ | CKSOM |  |  | DNSOM |  |  |

| 10 | 8 | 480 | $\mathbf{4 0 0}$ | 80 | 160 | $\mathbf{1 2 8}$ | 32 |
| 20 | 12 | 1440 | $\mathbf{1 3 0 8}$ | 132 | 480 | $\mathbf{4 2 0}$ | 60 |
| 18 | 30 | 3240 | $\mathbf{3 0 4 0}$ | 200 | 1080 | $\mathbf{9 8 8}$ | 92 |

Based on the visualisation in Table 4.12, the DNSOM model can represent the surface with different width, $n_{x}$ and length, $n_{y}$ of the grid. Meanwhile, the CKSOM model fails to generate the correct surface when different grid sizes were used as shown in Table 4.12 although it achieved lower QE compared to DNSOM model. Figure 4.9 illustrates the surface generated by the CKSOM model contains holes and the holes are highlighted with the rectangles. The holes appeared because the structure of the CKSOM model contains holes at the boundary as highlighted by the rectangle in Figure 4.10. Holes appeared on the CKSOM model because the length and width of the bottom, left and back views were assigned with different values.

In contrast, Figure 4.11 illustrates the surface generated by the DNSOM model without holes.

Figure 4.9: Visualisation for the CKSOM model with grid size, $n_{x}=18$ and $n_{y}=\mathbf{3 0}$ given the spindle data

Figure 4.10: The CKSOM model with grid size, $n_{x}=18$ and $n_{y}=30$

This is because the boundary of the 2-D SOMs used to build the structure of the DNSOM model are connected as shown in Figure 4.12. Thus, the DNSOM model has overcome the limitation of the CKSOM model. Besides, smoother surface was generated when the number of vertices used to represent the surface increases.

Apart from testing and validating the DNSOM model in organising the data with different $n_{x}$ and $n_{y}$ on primitive shapes, additional experiment was performed to further explore the capability of the DNSOM model in organising complex data such as the Stanford bunny data [46]. The DNSOM model with the grid size, $n=30$ was used to organise the Stanford bunny data.

The same initial learning rate, initial radius and maximum iteration from Table 4.1 were applied. The initial radius was set to the half of the minimum value between $n_{x}$ and $n_{y}$ and it was proposed in [129].

Figure 4.11: Visualisation for the DNSOM model with grid size, $\boldsymbol{n}_{x}=18$

$$
\text { and } n_{y}=30 \text { given the spindle data }
$$

Figure 4.12: The DNSOM model with grid size, $\boldsymbol{n}_{x}=18$ and $n_{y}=\mathbf{3 0}$

Figure 4.13 shows that the DNSOM model failed to generate the ear of the Stanford bunny data correctly as marked by the circle because the winner neurons and their neighbouring neurons were not updated during the learning process. The QE and TE of the experiment were 0.049694 and 0.225400 respectively. The CPU time of the experiment was 5.386289 seconds. It is noticed that the Deep Learning (DL) SOM in [42] also faced the same
problem while reconstructing the Stanford bunny data. Nevertheless, both models can reconstruct the overall shape of the Stanford bunny.

Figure 4.13: Visualisation of Stanford bunny data for DNSOM model with grid size, $n=\mathbf{3 0}$ showing the incorrect representation of the ear as marked by the circle

Besides, equations were derived to compute the NON, NOV and NOR of the DNSOM model. They were used to generate the model. Different grid sizes were used to verify and validate the equations. As suggested in [25], the area formula (Area $=a \times b$ ) can be used to calculate the total number of neurons for each map in which $a$ is the length and $b$ is the width of the grid. In this experiment, $a$ was represented as $n_{y}$ and $b$ was represented as $n_{x}$. Thus, when $a=5$ and $b=4$, then the area of a map would be Area $=a \times b=5 \times 4=$ 20. Since, two maps were used to create the model, the total number of neurons used to create the model would be $2 \times 5 \times 4=40$.

Furthermore, manual calculation can be performed on Figure 4.3 to calculate the NON, NOV and NOR. Each box in Figure 4.3 indicates a neuron and the number in each box indicates the Class Number of each neuron. By
counting all the boxes without considering the Class Number, the total number of neurons, NON was obtained. Meanwhile, the total number of output neurons, NOV or the neurons used to represent the surface can be obtained by counting the boxes with distinct Class Number. By counting the redundant Class Number once, the total number of redundancies, NOR was obtained. The redundant neurons would not be used to represent the surface. With the use of the manual calculation, the model in Figure 4.3 obtained the results of NON $=40, \mathrm{NOV}=26$ and $\mathrm{NOR}=14$. The same way was used to calculate the NON, NOV and NOR manually for various $n_{x}$ and $n_{y}$, and the results were tabulated in Table 4.14. Additionally, the NON, NOV and NOR equations were derived using Arithmetic Progression and the derivation is shown in Table 4.15. The equation of NON, NOV and NOR can be proved and validated by comparing the results from Table 4.14 and Table 4.15. The results show that the equations derived are valid and can be used to calculate the NON, NOV and NOR of the DNSOM model when different width, $n_{x}$ and length, $n_{y}$ of the grid are set for the model.

### 4.4 Summary

A new SOM model was proposed through the merging of two 2-D SOMs. The DNSOM model can organise unstructured data and generate closed surface without holes. It overcomes the holes problem in 2-D SOM, the connectivity problem in 3-D SOM and the grid size problem in CKSOM. As mentioned previously, the output of the DNSOM model cannot be used directly as the standard representation in the field of computer-aided geometric design (CAGD). Previous works have applied the NURBS surface approximation approach on the output of the SOM models, so that the SOM models can be used in the field of CAGD. Previous works have also shown that gaps would appear when the approach was applied on multiple SOM. Hence, Chapter 5
focuses in overcoming the limitation of the NURBS surface approximation approach.

## CHAPTER 5

## THE IMPROVED NURBS SURFACE APPROXIMATION APPROACH

### 5.1 Overview

This chapter proposes a NURBS surface approximation approach to overcome the limitations of the NURBS surface approximation approach on the Double Net Self-Organising Map (DNSOM) model. In [23], the NURBS surface approximation approach was applied on the output of the Cube Kohonen SelfOrganising Map (CKSOM), a model formed through the merging of six 2-D SOMs. The approach applied NURBS on each of the CKSOM surfaces data separately. It is named as the conventional approach here. Six surfaces data were involved because CKSOM is made up of six 2-D SOMs. Consequently, gaps were discovered when NURBS surface approximation approach was applied on the outputs of CKSOM because the surface data at the edges of both surfaces do not have the same value. When the conventional approach was applied on the DNSOM surfaces data, the same problem occurred. Therefore, an improved surface approximation approach was proposed to overcome the problem. This chapter also compares the performance between the conventional and improved approaches.

### 5.2 System Flow of the Improved Surface Approximation Approach

 The system flow of the improved NURBS surfaces approximation approach is illustrated in Figure 5.1. The system flow of the improved surface approximation approach was adapted from [23] because it was applied on multiple SOMs. Improvements were made to the perform parameterisation, perform control points calculation and perform surfaces error calculation stepsas shown in the dashed boxes in Figure 5.1 in order to generate the NURBS surfaces without gaps.

-- - Improvements
Figure 5.1: Flowchart for the improved NURBS surfaces approximation

## approach

### 5.2.1 Acquiring Data

The data used in this approach were the 3-D structured closed surface data of the cube, sphere, spindle, oiltank and talus bone generated by the DNSOM model with the grid size, $n_{\mathrm{x}}=n_{\mathrm{y}}=20$ and $n_{\mathrm{x}}=18, n_{\mathrm{y}}=30$. The DNSOM surfaces data with these grid sizes were used because they were large enough to generate a set of control nets (CNs) and they achieved the lowest QE as shown in Table 4.6. The model was constructed using two 2-D SelfOrganising Maps (SOMs) to organise the unstructured closed surface data. The data were used in the conventional and the improved NURBS surface approximation approaches. To avoid non-linear problem, the weights, $w_{i, j}$,
were set to 1 when applying the conventional and the improved NURBS surface approximation approaches [133]. When $w_{i, j}$ are set to 1 , the NURBS surface is reduced to B-Spline surface [134]. As suggested by Kumar, Kalra and Dhande [26], a curve or surface must have at least cubic degree (order 4) to represent generic 3-D entities. Iglesias, Gálvez and Collantes [135] also suggested the use of cubic degree (order 4) because low-degree curve or surface has limited flexibility in controlling its shape while the high-degree curve or surface can cause unwanted wiggles and require more computation. Therefore, cubic degree is used in this research based on these suggestions.

### 5.2.2 Parameterisation and Knot Vector Generation

Parameterisation and knot vector generation is required in NURBS surface approximation approach to generate the NURBS surface and it was performed on each of the surface data separately to obtain the control points used to generate the NURBS surfaces for each of the data. The steps included in this process are perform parameterisation and generate knot vectors.

### 5.2.2.1 Perform Parameterisation

Given the DNSOM surface data, parameterisation methods were used to obtain the parameters ( $u$ and $v$ ) for each surface. Let $U_{s i}$ and $V_{s j}$ be the vectors containing the parameter $u$ in horizontal direction with $n+1$ columns of the DNSOM surface data and parameter $v$ in vertical direction with $m+1$ rows of the DNSOM surface data respectively, where $n$ and $m$ are the column and row indexes. Equation 5.1 and Equation 5.2 were adapted from [23], which were the modifications of the equations proposed by Shene [136] by adding the surface number. Two surface numbers were allocated because the DNSOM
model is comprised of two 2-D SOMs. The bottom surface was represented with surface number, 1 and the top surface was represented with surface number, 2 because the SOMs are arranged from bottom to top. Parameterisation methods such as Uniform, Chord Length, Centripetal and Exponential methods were used to evaluate their performances. After the parameters ( $U_{s i}$ and $V_{s j}$ ) for each surface were obtained, the average parameters of each row and column for each surface were used to compute the knot vectors.

$$
\begin{align*}
& s_{s i}=\frac{u_{s i, 0}+u_{s i, 1}+u_{s i, 2}+\cdots+u_{s i, n}}{n+1}  \tag{5.1}\\
& r_{s j}=\frac{v_{s 0, j}+v_{s 1, j}+v_{s 2, j}+\cdots+v_{s m, j}}{m+1} \tag{5.2}
\end{align*}
$$

where $s_{s i}$ are the average parameters in the $u$ direction, $r_{s j}$ are average parameters in the $v$ direction, $s$ is the surface number, $i$ is the row and $j$ is the column.

However, the use of average parameters to generate the knot vectors would cause the generation of the NURBS surfaces with gaps at the edges of each surface. The parameters for both surfaces in the $u$ and $v$ directions were standardised with Equation 5.3 and Equation 5.4 so that the control points at the edges of the CNs has the same value. When the control points at the edges of the CNs has the same value, the surface data located at the edges of both surfaces would have the same value too.

$$
\begin{align*}
& S_{i}=\frac{s_{1 i}+s_{2 i}}{2}  \tag{5.3}\\
& R_{j}=\frac{r_{1 j}+r_{2 j}}{2} \tag{5.4}
\end{align*}
$$

where $S_{i}$ is the standardised parameters for both surfaces in the $u$ direction, $R_{j}$ is the standardised parameters for both surfaces in the $v$ direction. $S_{i}$ were assigned to $s_{1 i}$ and $s_{2 i}$, and $R_{i}$ was assigned to $r_{1 j}$ and $r_{2 j}$. The standardised parameters would be used to generate the knot vectors instead of the average parameter for the improved approach in this research.

### 5.2.2.2 Generate Knot Vectors

After the parameter values were obtained via the parameterisation methods, the averaging knot vector method was used to generate the knot values of each surface. The method was suggested by Jiang and Wang [134], Forkan and Shamsuddin [32], Lim and Haron [23], Makhlouf, Elloumi, Louhichi and Deneux [137] and adapted from Shene [136]. The method was used in this research because the knot vector can be generated with Equations $2.9-2.11$ in Section 2.3.2. The equations were applied to the standardised parameters, $S$ and $R$ to generate the knot vectors for each surface. Since the standardised parameters were used in the generation of knot vectors for both surfaces, both surfaces would have same knot vectors.

### 5.2.3 Calculation of Basis Functions, Control Points and Surfaces Data

### 5.2.3.1 Perform Basis Function Calculation

The basis function ( $N_{u}$ and $N_{v}$ ) for each surface was calculated after the generation of knot vectors. The basis function is required to obtain the control
points in the next step. The basis function of each surface was computed with Equation 2.3 from Chapter 2, Section 2.3.2.

### 5.2.3.2 Perform Control Points Calculation

The calculation of control points for each surface was performed according to their basis function ( $N_{u}$ and $N_{v}$ ). The equation is referred from Sarfraz and Riyazuddin [138], and Zhang, Feng and Cui [90], and adapted from Lim and Haron [23].

$$
\begin{gather*}
N_{u} P N_{v}=D  \tag{5.5}\\
N_{u}^{T} N_{u} P N_{v} N_{v}^{T}=N_{u}^{T} D N_{v}^{T} \\
N_{u}^{\prime} P N_{v}^{\prime}=N_{u}^{T} D N_{v}^{T} \\
N_{u}^{\prime-1} N_{u}^{\prime} P N_{v}^{\prime} N_{v}^{\prime-1}=N_{u}^{\prime-1} N_{u}^{T} D N_{v}^{T} N_{v}^{\prime-1} \\
P=N_{u}^{\prime-1} N_{u}^{T} D N_{v}^{T} N_{v}^{\prime-1} \tag{5.6}
\end{gather*}
$$

where $N_{u}$ and $N_{v}$ are the basis function for each surface, $P$ is the control point, $D$ is the DNSOM model closed surface data, $N_{u}{ }^{T}$ and $N_{v}{ }^{T}$ is the transpose basis function, $N_{u}{ }^{\prime}$ is the product of $N_{u}{ }^{T}$ and $N_{u}, N_{v}{ }^{\prime}$ is the product of $N_{v}$ and $N_{v}{ }^{T}, N_{u}{ }^{\prime}{ }^{\prime}$ ${ }^{1}$ is the inverse of $N_{u}{ }^{\prime}$ and $N_{v}{ }^{-1}$ is the inverse of $N_{v}{ }^{\prime}$.

Equation 5.5 was used in the improved approach to compute the control points of each surface. The computation of control points for each surface was conducted separately because two DNSOM surfaces data were involved. After the computation of the control points for both surface, different coordinates were produced. Hence, the concept of Index Vector and Class Number from Chapter 4 were applied to group the control points at the edges of the CNs before the standardisation of the control points. Index Vector are allocated to both CNs. Figure 5.2 shows the Index Vector and Class

Number of each control point for the bottom and top CNs given the $C N_{x}=3$ and $C N_{y}=4$ where $C N_{x}$ and $C N_{y}$ are the column and row of the CN respectively. The Index Vector of each control point is comprised of the index values, $i$ and $j$. Class Number was allocated from bottom to top, left to right of each surface. Each Class Number followed the sequence from bottom to top surface. If $i=0$ or $i=C N_{x}-1$ or $j=0$ or $j=C N_{y}-1$ for the Index Vector of each control point in the top CN , the control point would be grouped into the same Class Number as shown in Figure 5.2. The index values, $i$ and $j$ of the control points that fulfilled the condition is bold in Figure 5.2.

(a) Bottom

(b) Top
$3 \times 4$ NURBS control net
Figure 5.2: Index Vector and Class Number for the control points in the

## bottom and top CNs given the $C N_{x}=3$ and $C N_{y}=4$

After computing the control points for each of the surfaces and grouping the control points into their respective Class Number, the control points with the same Class Number are standardised by summing and averaging them accordingly. The standardised control points, $P_{\text {avg }}^{e}$ were assigned and replaced the control points having the same Class Number to close the gaps after computed using Equation 5.7.

$$
\begin{equation*}
P_{a v g}^{e}=\frac{P_{1}^{e}+P_{2}^{e}}{2} \tag{5.7}
\end{equation*}
$$

where $P_{1}^{e}$ and $P_{2}^{e}$ are the control point at the edge of the bottom and top CNs respectively, $P_{\text {avg }}^{e}$ is the standardised control point for the control point at the edge of the bottom and top CNs.

Similar to the conventional approach, the control points located at the four corners of bottom and top CNs of the improved approach must pass through the points positioned at the four corners of the bottom and top surfaces of the DNSOM model respectively. Class Number from the previous chapter was utilised to obtain the corners of the bottom and top CNs, and the corners of the bottom and top surfaces of the DNSOM surface data. Figure 5.2 shows the bottom and top surfaces of the DNSOM model, and the top and bottom CNs of the improved approach respectively. The red boxes in the figure are the corners of the bottom and top surfaces of the DNSOM surface data and CNs. Meanwhile, the grey and yellow boxes in the figure are the coordinates and control points at the edges of the DNSOM data and CNs respectively. The number in each box in the figure is the Class Number of the coordinates and control points. The $D_{1}, D_{2}, D_{3}$ and $D_{4}$ in Figure 5.3 are the points located at the four corners of the bottom and top surfaces data of the DNSOM model. Besides, $C_{1}, C_{2}, C_{3}$ and $C_{4}$ in Figure 5.3 are the control points located at the four corners of the bottom and top CNs.

Figure 5.3: Bottom and top surfaces and CN of the DNSOM model and

## NURBS

Equations $5.8-5.11$ were the general equations derived to compute the Class Number of each control points at the corner of the CN.

$$
\begin{gather*}
c_{1}=(n x)^{0}  \tag{5.8}\\
c_{2}=n y  \tag{5.9}\\
c_{3}=n y(n x-1)  \tag{5.10}\\
c_{4}=n x n y \tag{5.11}
\end{gather*}
$$

where $c_{i}$ are the corners of the CN and DNSOM surfaces data, $n x$ and $n y$ are the width and length of the CN or the DNSOM surfaces data respectively.

Manual calculation was performed on the bottom and top CNs as demonstrated in Figure 5.4 to obtain the Class Number of each control points. Each number in the boxes represents the Class Number of the control points from the CNs of different width, $C N_{x}$ and length, $C N_{y}$.

### 5.2.3.3 Perform Surfaces Data Calculation

The surfaces data was calculated after the basis functions, control points and surfaces data were calculated. Equation 5.12 was used to compute the NURBS surfaces data.

$$
\begin{equation*}
N_{u} P N_{v}=D \tag{5.12}
\end{equation*}
$$

where $N_{u}$ and $N_{v}$ are the basis functions in $u$ and $v$ directions respectively, $P$ is the control points and $D^{G}$ is the NURBS surfaces data.

### 5.2.4 Calculation of Surfaces Error

The surface error for the improved approach was calculated with Equation 5.13 and the equation was based on the Class Number and Euclidean distance formula. The use of Euclidean distance as the evaluation metric was suggested by Piegl and Tiller [139], Adi, Shamsuddin and Ali [140] and Lim and Haron [23]. The total Class Number is the total number of vertices used by the improved approach to represent the surface of the data. The total number of output neurons of the DNSOM model, NOV is used in Equation 5.13 because it is noticed that the equation used to compute the NOV of the DNSOM model can be used to calculate the total number of vertices used by the improved approach to represent the surface of the data. Hence, the total Class Number is equal to NOV.

$$
\begin{equation*}
E=\sum_{i=1}^{\text {NOV }}\left|D_{i}-D_{i}^{G}\right| \tag{5.13}
\end{equation*}
$$

where $D_{i}$ and $D_{i}{ }^{G}$ are the DNSOM surface data and improved NURBS surface data for Class Number respectively and the NOV is calculated with Equation 4.2 in Chapter 4, Section 4.2.3.

### 5.3 Analysis and Discussion

This section analyses and discusses the results of the research. Various sizes of control net ( CN ) and parameterisation methods were used to examine their
performance on the conventional and improved NURBS surface approximation approach.

The visualisation of DNSOM model data using the conventional (A) and improved (B) NURBS surface approximation approaches with various sizes of CN and parameterisation methods for the $n_{x}=20$ and $n_{y}=20$, and for the $n_{x}=18$ and $n_{y}=30$ are shown in Appendix G and Appendix H respectively. Based on the results in Appendix G and Appendix H, better surface is generated when the size of CN increases. Table 5.2 and Table 5.3 show the visualisation of the spindle data for the conventional and improved NURBS surface approximation approach in Appendix G and Appendix H respectively given the same and different grid size.

As shown from the visualisation in Table 5.2 and Table 5.3, various parameterisation methods were successfully implemented in conventional and improved NURBS surface approximation approach. Based on the visualisation in Table 5.2 and Table 5.3, the surfaces generated are quite similar to the output of the DNSOM model although different grid size and different parameterisation were used. No gaps were noticed after applying the improved approach and the shape of the data was not affected. Therefore, parameterisation methods can be applied on the improved NURBS surface approximation approach. In addition, to further test the performance of the parameterisation methods, quantitative measurement was used.

Table 5.2: Visualisation of the spindle data for the conventional NURBS surface approximation approach given the same and different grid size

| CN | $18 \times 18$ | $16 \times 28$ |
| :---: | :---: | :---: |
| Uniform |  |  |
| Chord Length |  |  |
| Centripetal |  |  |
| Exponential |  |  |

Appendix E show the surface error of the conventional and improved approaches for $7 \mathrm{CN}(6 \times 6,8 \times 8,10 \times 10,12 \times 12,14 \times 14,16 \times 16,18 \times 18)$ and data when the $n_{x}$ and $n_{y}$ are equal to 20 . Appendix F show the surface error of the conventional and improved approaches for $7 \mathrm{CN}(4 \times 16,6 \times 18,8$ $\times 20,10 \times 22,12 \times 24,14 \times 26,16 \times 28)$ and data when the $n_{x}$ is equal to 18 and $n_{y}$ is equal to 30 respectively.

Table 5.3: Visualisation of the spindle data for the improved NURBS surface approximation approach given the same and different grid size

| CN | $18 \times 18$ | $16 \times 28$ |
| :---: | :---: | :---: |
| Uniform |  |  |
| Chord <br> Length |  |  |
| Centripetal |  |  |
| Exponential |  |  |

Table 5.4 shows the summarised results of the methods in Appendix E that achieved the least surface error in conventional approach for each data when the $n_{x}$ and $n_{y}$ is 20 . Since there were $7 \mathrm{CNs}(6 \times 6,8 \times 8,10 \times 10,12 \times$ $12,14 \times 14,16 \times 16,18 \times 18$ ) for each data and parameterisation method when the $n_{x}$ and $n_{y}$ is 20 , the method that achieved the least surface error for 6 CNs is recorded as $6 / 7$. When the surface error is small, the NURBS surfaces data are approximated more towards the DNSOM surface data. The Exponential method performed better than the other methods given the cube,
sphere and oiltank data because it achieved the lowest surface error for $3 / 7$, $4 / 7$ and $4 / 7$ CNs respectively. Apart from that, the Chord Length method performed better than the other methods because it obtained the least surface error for most of the CNs which is $4 / 7$ for both spindle and talus bone data. Exponential method was the most suitable method for conventional approach because it achieved the highest number of minimum surface error which is 15/35.

Table 5.4: Summarised results of the methods that achieved the least surface error in conventional approach for each data given the $\boldsymbol{n}_{\boldsymbol{x}}=\mathbf{2 0}$

$$

| Sphere | $0 / 7$ | $3 / 7$ | $0 / 7$ | $4 / 7$ |
| Spindle | $0 / 7$ | $4 / 7$ | $0 / 7$ | $3 / 7$ |
| Oiltank | $0 / 7$ | $3 / 7$ | $0 / 7$ | $4 / 7$ |
| Talus <br> Bone | $0 / 7$ | $4 / 7$ | $2 / 7$ | $1 / 7$ |
| Total | $2 / 35$ | $14 / 35$ | $4 / 35$ | $15 / 35$ |

Table 5.5 shows the summarised results of the methods in Appendix E that achieved the least surface error in improved approach for each CN and data when the $n_{x}$ and $n_{y}$ are 20 . The Centripetal and Exponential methods performed better than the other methods because they achieved the least surface error for $3 / 7$ CNs given the cube data. The Exponential method also performed better compared to other methods as it achieved the least surface error for $4 / 7$ CNs given the oiltank data. Besides, the Chord Length method achieved better results than the other methods given the sphere, spindle and
talus bone data because they achieved the least surface error for $4 / 7,5 / 7$ and $5 / 7$ CNs. Based on the results in Table 5.5, the Chord Length method outperformed the other methods for improved approach as it achieved the highest number of least surface error which is $18 / 35$.

Table 5.6 shows the summarised results for conventional and improved approaches when the $n_{x}$ and $n_{y}$ are 20 in Appendix E. Table 5.6 records the total number of least surface error achieved by the approaches for the 7 CNs of each data and parameterisation methods. Since there are 7 CNs for each parameterisation method, the approach that achieved the least surface error for 6 CNs is recorded as $6 / 7$ in Table 5.6. Based on the results in Table 5.6, the improved approach performed better than the conventional approach as it achieved the highest number of minimum surface error which is $126 / 140$.

Table 5.6: Summarised results for conventional (A) and improved (B)
approaches given the $\boldsymbol{n}_{x}=20$ and $\boldsymbol{n}_{\boldsymbol{y}}=20$

Table 5.7 shows the summarised results of the methods in Appendix F that achieved the least surface error in conventional approach for various data when the $n_{x}$ and $n_{y}$ are 18 and 30 respectively. Since there are $7 \mathrm{CNs}(4 \times 16,6$ $\times 18,8 \times 20,10 \times 22,12 \times 24,14 \times 26,16 \times 28)$ for each data and parameterisation method when the $n_{x}$ and $n_{y}$ are 18 and 30 respectively, the method that achieved the least surface error for 6 CNs is recorded as $6 / 7$. The Uniform method outperformed the other methods given the cube data as it achieved the least surface error for $3 / 7$ CNs. Meanwhile, the Chord Length method performed better than the other methods for the sphere data as it achieved the least surface error for $3 / 7 \mathrm{CNs}$. For the spindle and oiltank data,
the Exponential method outperformed the other methods because it achieved the least surface error for $4 / 7$ and $4 / 7$ CNs respectively. For the talus bone data, the Centripetal method performed better than the other method because it acquired the least surface error for $3 / 7$ CNs. Based on the results in Table 5.7, the Exponential method outperformed the other methods for conventional approach as it achieved the highest number of minimum surface error which is 13/35.

Table 5.7: Summarised results of the methods that achieved the least surface error in conventional approach for various data and sizes of $\mathbf{C N}$

$$
\text { given the } n_{x}=18 \text { and } n_{y}=30
$$

| Data | Uniform | Chord Length | Centripetal | Exponential |
| :---: | :---: | :---: | :---: | :---: |
| Cube | $3 / 7$ | $1 / 7$ | $2 / 7$ | $1 / 7$ |
| Sphere | $0 / 7$ | $3 / 7$ | $2 / 7$ | $2 / 7$ |
| Spindle | $0 / 7$ | $3 / 7$ | $0 / 7$ | $4 / 7$ |
| Oiltank | $0 / 7$ | $3 / 7$ | $0 / 7$ | $4 / 7$ |
| Talus <br> Bone | $1 / 7$ | $1 / 7$ | $3 / 7$ | $2 / 7$ |
| Total | $4 / 35$ | $12 / 35$ | $7 / 35$ | $13 / 35$ |

Table 5.8 is the summarised results of the methods in Appendix F that achieved the least surface error in the improved approach for various data and sizes of CN when the $n_{x}$ and $n_{y}$ are 18 and 30 respectively. Apart from that, the Uniform, Chord Length and Centripetal methods performed better than the Exponential method as they acquired the least surface error for most of the CN given the cube data which is $2 / 7$. For the sphere data, the Chord Length and Centripetal methods performed the best because they achieved the least surface error for $3 / 7$ CNs. For the spindle data, the Chord Length method also
performed better than the other method because it obtained the least surface error for $6 / 7$ CNs. Besides, the Chord Length method achieved better results compared to other methods for the oiltank data because it acquired the least surface error for $4 / 7$ CNs. Furthermore, the Centripetal method performed better than the other methods for the talus bone data as it obtained the least surface error for $3 / 7$ CNs. According to the results shown in Table 5.8, Chord Length method is the most suitable method for the improved approach when the $n_{x}$ and $n_{y}$ are 18 and 30 because it achieved the highest number of least surface error which is $17 / 35$.

Table 5.8: Summarised results of the methods that achieved the least surface error in the improved (B) approach for various data and sizes of CN given the $\boldsymbol{n}_{x}=18$ and $\boldsymbol{n}_{\boldsymbol{y}}=\mathbf{3 0}$

|  | Chord Length | 0/7 | $7 / 7$ |
|  | Centripetal | 1/7 | 6/7 |
|  | Exponential | 0/7 | $7 / 7$ |
|  |  | 22/140 | 118/140 |

According to the results in Table 5.4 and Table 5.7, the Exponential method was the best method for the conventional approach as it achieved the least surface error for most of the experiments given the same and different grid size. Based on the results in Table 5.5 and Table 5.8, the Chord Length method was the best method for the improved approach because it obtained the highest number of minimum surface error given the same and different grid size. The surface error of both approaches also decreases when the size of CN increases because there were more control points available to adjust the shapes. This proves that surfaces of the approaches were approximated more towards the output of the DNSOM model when the size of the CN increases
and better surfaces were generated. Uniform method performed the worst because it was not suitable for data that were not distributed linearly [89]. Meanwhile, the Centripetal method was better than the Chord Length method in handling sharp turns [88] whereas the Exponential method has the property of Centripetal and Chord Length methods since the value of its $\alpha$ in Equation 2.8, Chapter 2 is 0.8 , which is between the value of $\alpha$ set for the Centripetal and Chord Length methods. So, the Chord Length method performed better than the Exponential method for most of the experiments because most of the data in this experiment do not have sharp turn. Therefore, based on the results in Table 5.5 and Table 5.8, Chord Length method was considered the best method in the improved approach because it achieved the least surface error for 35/70 results.

The NURBS surface approximation approach with improvements were proposed to overcome the problem faced by the conventional NURBS surface approximation approach [23] when it was applied on the DNSOM surfaces data. Gaps were observed at the edges of both surfaces after the approach was applied on the output of the model as shown in Figure 5.5.

It was observed that when the size of the CN increases, the size of the gaps reduces and better surfaces were generated. Improvements were made to the perform parameterisation and perform control points calculation processes of the conventional approach to avoid the gaps from appearing. No gaps were found after the implementation of the improved approach as shown in Figure 5.6 because the boundaries between the NURBS surfaces are merged during the perform parameterisation and perform control points calculation steps.

Figure 5.5: Image of NURBS surfaces generated with conventional approach for $18 \times 18 \mathrm{CN}$ and uniform parameterisation method given the cube data

Hence, lower surfaces error was obtained for the improved approach compared to the conventional approach.

Figure 5.6: Image of NURBS surfaces generated with improved approach for $18 \times 18 \mathrm{CN}$ and uniform parameterisation method given the cube data

### 5.4 Summary

The conventional NURBS surface approximation approach was proven applicable on the output of the DNSOM model. Exponential method was the best method for the conventional approach. But gaps were observed at the edges of both surfaces when the approach was applied on the output of the model. The size of the gaps was reduced and better surfaces were generated when the size of CN increases for the conventional approach. Improvements were made to the perform parameterisation and perform control points calculation processes of the conventional approach to close the gaps. No gaps were found after the implementation of the improved NURBS surface approximation approach. The Chord Length method is the best method for the improved approach. Besides, the improved approach also performed better than the conventional approach because it achieved the least surface error for most of the experiments. Therefore, the improved approach performed better than the conventional approach. The surface error of both approaches decreases when the size of CN increases. This demonstrates that the surfaces generated is better when the size of the CN increases. However, more accurate surface can be generated by tuning the control points of NURBS with optimisation technique as shown in [28].

## CHAPTER 6

## OPTIMISATION OF THE IMPROVED NURBS SURFACE APPROXIMATION APPROACH

### 6.1 Overview

This chapter demonstrates the system flow, analyses and discusses the optimisation of control points of the improved NURBS surface approximation approach using optimisation techniques such as Genetic Algorithm (GA), Differential Evolution (DE) and Particle Swarm Optimisation (PSO). Optimisation techniques were applied because the NURBS surfaces generated were not the optimum as they were generated mathematically. Thus, optimisation techniques were applied to generate the improved NURBS surfaces with higher accuracy by optimising the control points of the improved NURBS surface approximation approach.

### 6.2 System Flow for the Optimisation of the Improved NURBS Surface Approximation Approach

This section discusses the system flow of GA, DE and PSO in optimising the control points. GA with Value Encoding, Tournament Selection, Uniform Crossover, Uniform Mutation and Weak Parent Replacement, DE and PSO with constriction factor and velocity clamping are used to optimise the control points. Based on the work in [141], GA with Tournament Selection, Uniform Crossover, flip mutation and Weak Parent Replacement achieved the highest number of minimum average fitness values. Therefore, the Tournament Selection and Uniform Crossover were used for the GA. The flip mutation was replaced with Uniform Mutation because flip mutation is not suitable for value
encoding GA. Besides, GA with the abovementioned operations was used because this research focuses in proving that GA can be used to optimise the control points of the improved approach. DE [33] was employed for the same purpose. The PSO with constriction factor and velocity clamping was used in this research because it achieved the best result in the work of Lim, Hoon and Song [34].

### 6.2.1 Data Acquisition

The data used in this research were the control points, basis function, surface data from improved NURBS surface approximation approach and DNSOM surface data. These data were needed to optimise the control points. Figure 6.1 is an example of the bottom and top $3 \times 4 \mathrm{CN}$ with several chosen control points. 1-D array was used to represent the control points and it was used as an input for the GA, DE and PSO. The representation of the control points in a 1D array is shown in Figure 6.2. The representation is based on Figure 6.1. Each control point, $P_{i}$ is in their coordinate form $\left(x_{i}, y_{i}, z_{i}\right)$, where $i$ is the Class Number. The concept of Class Number was used in this research to group the redundant control points accordingly. In GA and DE, the 1-D array representing the control points is generally known as chromosome. Meanwhile, the array is known as particle in PSO. To optimise the control points, individuals or particles was generated initially by summing the value of $x, y$ and $z$ coordinates of each control point with their respective randomly generated value within the range of $\left[-5 \times 10^{-6}, 5 \times 10^{-6}\right]$.

## chromosome or particle

### 6.2.2 Parameter Settings

Table 6.1 presents the common parameter settings for GA, DE and PSO, and their respective parameter settings except the Number of Dimension, $d$ and the Control Point Coordinate Range are referred from [34], [141], [142]. The Number of Generation is the maximum generation and it was the termination criterion used in this research. The Population Size, $n$ is set to 40 . The Number of Dimension for the chromosome and particle is NOV, where NOV is the number of control point used to generate the surface data by the improved NURBS surface approximation approach. The concept of Class Number is utilised to group the redundant control points at the edges of the control net (CN) of the approach. Thus, the NOV would be the total number of Class Number. The equation used to compute the NOV can be referred from Equation 4.2 in Chapter 4, Section 4.2 .3 by substituting the width, $n_{x}$ and
length, $n_{y}$ of the grid for DNSOM model with the width, $C N_{x}$ and length, $C N_{y}$ of the CN respectively. For GA, the Crossover Probability, $P_{c}$ and Mutation Probability, $P_{m}$ used are 0.7 and 0.01 . Meanwhile, the Crossover Probability and Differential Weight, $F$ of DE is 0.01 and 0.8 . The acceleration constants, $c_{1}$ and $c_{2}$ of the PSO was set to 2.05 . The maximum velocity and position of the PSO was set to half of the range of the data set and the range of the data set respectively. Maximum velocity was used as the velocity clamping and maximum position is set to prevent the particle from moving beyond the boundaries of the search space. The velocity of each particle was initialised to 0. The Constriction Factor, $K$ of the PSO was set to 0.729 . The GA, DE and PSO were run 10 times for each experiment to show that different fitness value is acquired at each run. Average fitness value and CPU time were computed from the fitness value of all the run for each of the experiment. A small range was set as the control point coordinate range because there would be lesser combination of control points. Consequently, it would be easier to find the best control points.

### 6.2.3 Fitness Function

The DNSOM surfaces data, $D^{O}$ is computed with Equation 6.1 and it is also defined by rewriting the Equation 5.12 in Chapter 5, Section 5.2.3.3.

$$
\begin{equation*}
N_{u} P^{o} N_{v}=D^{o} \tag{6.1}
\end{equation*}
$$

where $N_{u}$ and $N_{v}$ are the basis function in $u$ and $v$ direction respectively, $P^{O}$ is the control points, and $D^{O}$ is the optimised NURBS surface data of the improved NURBS surface approximation approach.

Table 6.1: Parameter settings

| No. | Parameter | Value |
| :--- | :--- | :---: |
| 1. | Number of Generation | 2000 |
| 2. | Population Size, $n$ | 40 |
| 3. | Number of Dimension, $d$ | NOV |
| 4. | Control Point Coordinate Range | $\left[-5 \times 10^{-6}, 5 \times 10^{-6}\right]$ |
| 5. | GA Crossover Probability, $P_{c}$ | 0.7 |
| 6. | GA Mutation Probability, $P_{m}$ | 0.01 |
| 7. | DE Crossover Probability | 0.8 |
| 8. | DE Differential Weight, $F$ | 0.3 |
| 9. | PSO Constriction Factor, $k$ | 0.729 |
| 10. | PSO Random Number $\left(r_{1}, r_{2}\right)$ | $[0,1]$ |
| 11. | PSO Maximum Velocity | Half of the range of the |
| dataset |  |  |

The fitness value in this research is calculated with the fitness function defined in Equation 6.2. The equation is based on Euclidean distance and Class Number and it is defined by rewriting the Equation 5.13 in Chapter 5, Section 5.2.4.

$$
\begin{equation*}
f(x)=\sum_{i=1}^{\text {NOV }}\left|D_{i}-D_{i}^{o}\right| \tag{6.2}
\end{equation*}
$$

where $D_{i}$ and $D_{i}{ }^{O}$ are the DNSOM surfaces data and optimised NURBS surface data from the improved NURBS surface approximation approach respectively.

### 6.2.4 Optimisation of Control Points

Optimisation of control points was performed with GA, DE and PSO. This section describes the system flow of GA, DE and PSO in optimising the control points.

### 6.2.4.1 Genetic Algorithm

The optimisation of control points with GA is described as follow:

1. A population of $n$ chromosomes are generated by summing the value of $x$, $y$ and $z$ coordinates of the control points with their respective randomly generated value within the range of $\left[-5 \times 10^{-6}, 5 \times 10^{-6}\right]$.
2. The fitness of each chromosome is evaluated with the fitness function, $f(x)$ in Equation 6.2.
3. Tournament Selection: 4 chromosomes are randomly selected and their fitness value are compared. Chromosome with the least fitness value is selected as the parent. Another round of tournament is conducted to find the next parent.
4. Uniform Crossover: A random number is generated and crossover will be executed if the random number is less than the Crossover Probability, $P_{c}$.
5. Uniform Mutation: A random number is generated and mutation will be executed if the random number is less than the Mutation Probability, $P_{m}$.
6. The fitness of the new offspring is evaluated with the fitness function, $f(x)$ in Equation 6.2.
7. Weak Parent Replacement: The fitness value of the parent will be compared with the fitness value of the offspring. If the fitness value of the offspring is smaller than that of its parent, the offspring will be included in the next generation. Else, the parent will be included.
8. If the termination criterion is not met, the algorithm continues with 3 . Else, the algorithm is terminated and the chromosome with the least fitness
value was produced. The fitness value of the best chromosome and the optimised surface data calculated from the chromosome were also produced.

### 6.2.4.2 Differential Evolution

The optimisation of control points with DE is described as follow:

1. A population of $n$ chromosomes are generated by summing the value of $x$, $y$ and $z$ coordinates of the control points with their respective randomly generated value within the range of $\left[-5 \times 10^{-6}, 5 \times 10^{-6}\right]$.
2. The fitness of chromosomes is evaluated using the fitness function, $f(x)$ in Equation 6.2.
3. Choose the target vector with index, $i=1$. Target vector with index, $i=1$ is the first chromosome in the population.
4. Mutation: For each target vector, a mutant vector is generated. Three indices $r_{1}, r_{2}$ and $r_{3}$ are randomly chosen from the population to form the mutant vector. The indices are integer and they are mutually different from one another. The indices are also different from the index, $i$.
5. Crossover: A random number is generated. If the random number is at least less than the DE Crossover Probability or equal to the randomly chosen index, the value at the current dimension of the mutant vector will be donated to the same dimension of the trial vector. Else, the value from the target vector will be donated to the trial vector. The crossover operation continues until the trial vector is constructed.
6. The fitness of trial vector is evaluated by using $f(x)$ in Equation 6.2.
7. Selection: If the fitness value of the trial vector is less than the target vector, the trial vector will be included in the next generation. Otherwise, the target vector is included.
8. If the index of the current target vector is at least less than $n$, choose the next target vector by incrementing the index by 1 and proceed with 4 . Otherwise, proceed to 9 .
9. If the termination criterion is not met, the algorithm continues with 3 . Otherwise, the algorithm is terminated and the chromosome with the least fitness value was produced. The fitness value of the best chromosome and the optimised surface data calculated from the chromosome were also produced.

### 6.2.4.3 Particle Swarm Optimisation

The optimisation of control points with PSO is described as follow:

1. $n$ particles are generated by summing the value of $x, y$ and $z$ coordinates of the control points with their respective randomly generated value within the range of $\left[-5 \times 10^{-6}, 5 \times 10^{-6}\right]$.
2. The fitness of the particles is evaluated with the fitness function, $f(x)$ in Equation 6.2.
3. The position of each particle is set as their best position. The particle with the smallest fitness value among $n$ particles is selected as the global best particle.
4. The velocity and position of the $n$ particles are computed and updated according to their best position and the position of the global best particle.
5. The fitness of the particles is evaluated with the fitness function, $f(x)$ in Equation 6.2.
6. The best position of each particle and the position of the best particle among the $n$ particles are updated.
7. If the termination criterion is not met, the algorithm continues with 3 . Otherwise, the algorithm will be terminated and the particle with the least fitness value was produced. The fitness value of the best particle and the optimised surface data calculated from the particle were also produced.

### 6.3 Analysis and Discussion

The outcome of the optimisation of control points using GA, DE and PSO were analysed and discussed in this section. The GA with Tournament Selection, Uniform Crossover, Uniform Mutation and Weak Parent Replacement, DE and PSO with constriction factor and velocity clamping were used to optimise the control points of the improved NURBS surface approximation approach.

Appendix I shows the visualisation of optimised surface data with the minimum (MIN) and maximum (MAX) optimised surface error obtained from the GA, DE and PSO and the visualisation of improved NURBS surface data (B) for the remaining data and parameterisation methods given the CNs of the same size. Table 6.2 shows the visualisation of optimised surface data with the minimum (MIN) optimised surface error obtained from the GA, DE and PSO and the visualisation of improved NURBS surface data $(B)$ for the spindle data, CN with the size of $18 \times 18$ and Chord Length method, where each of the CN are of the same length and width.

Table 6.2: Visualisation of MIN optimised surface data of GA, DE and PSO with the same length and width

| CN | $18 \times 18$ |
| :---: | :---: |
| GA |  |
| DE |  |
| PSO |  |
| B |  |

Appendix J shows the visualisation of optimised surface data with the minimum (MIN) and maximum (MAX) optimised surface error obtained from the GA, DE and PSO and the visualisation of improved NURBS surface data (B) for the remaining data and parameterisation methods given the CNs of different size. Table 6.3 shows the visualisation of optimised surface data with the minimum (MIN) optimised surface error obtained from the GA, DE and PSO and the visualisation of improved NURBS surface data $(B)$ for the spindle data, CN with the size of $16 \times 28$ and Chord Length method, where each of the CN are of the same length and width.

As shown from the visualisation in Table 6.2 and Table 6.3, GA, DE and PSO was successfully implemented on the improved approach. When the size of CN increases, better improved NURBS surfaces were generated. Based on the visualisation in Table 6.2 and Table 6.3, correct surfaces were generated and they were quite similar to the improved NURBS surfaces. Besides, the correct surfaces can be generated although different grid size, different parameterisation, different optimisation methods were used. No gaps were noticed after optimisation and the shape of the data was not affected. Therefore, optimisation techniques can be applied on the improved NURBS surface approximation approach. In addition, to further test the performance of the optimisation methods, quantitative measurement was used.

Appendix K and Appendix L show the experimental results for GA, DE and PSO via the optimisation of CN with same and different grid size.

Table 6.3: Visualisation of MIN optimised surface data of GA, DE and PSO with different length and width

The experimental results provide information on average (AVG), minimum (MIN) and maximum (MAX) optimised surface error obtained for various parameterisation methods and data sets. Table 6.4 shows the summarised results of the techniques in Appendix K that achieved the least average (AVG) optimised surface error for various data, methods and sizes of CN when the $n_{x}$ and $n_{y}$ are 20 . As shown in the Table 6.4, 7 is referring to the various sizes of $\mathrm{CN}(6 \times 6,8 \times 8,10 \times 10,12 \times 12,14 \times 14,16 \times 16,18 \times 18)$ of each parameterisation method. Therefore, the total number of summarised results is 140.

Table 6.4: Summarised results of the techniques that achieved the least average (AVG) optimised surface error for various data, methods and sizes of CN given the $\boldsymbol{n}_{x}=20$ and $\boldsymbol{n}_{\boldsymbol{y}}=20$

Furthermore, Table 6.7 shows the summarised results of the techniques in Appendix N that achieved the least average (AVG) CPU time for various data, methods and sizes of CN given the $n_{x}$ and $n_{y}$ are 18 and 30 respectively.

Table 6.7: Summarised results of the techniques that achieved the least average (AVG) CPU time for various data, methods and sizes of CN given the $n_{x}=18$ and $n_{y}=30$

| Data | Parameterisation <br> Method | GA | DE | PSO |
| :---: | :---: | :---: | :---: | :---: |
|  | Uniform | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Chord Length | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Centripetal | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Exponential | $7 / 7$ | $0 / 7$ | $0 / 7$ |
| Sphere | Uniform | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Chord Length | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Centripetal | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Exponential | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Uniform | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Chord Length | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Centripetal | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Exponential | $7 / 7$ | $0 / 7$ | $0 / 7$ |
| Talus Bone | Uniform | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Chord Length | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Centripetal | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Exponential | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Uniform | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Chord Length | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | Centripetal | $7 / 7$ | $0 / 7$ | $0 / 7$ |
| Total | Exponential | $7 / 7$ | $0 / 7$ | $0 / 7$ |
|  | - | $140 / 140$ | $0 / 140$ | $0 / 140$ |

Thus, the overall results for optimised surface errors of GA, DE and PSO are reflected in Table 6.8. The overall number of results given the Table 6.4 and Table 6.5 is 280.

Table 6.8: Overall results for optimised surface errors of GA, DE and PSO

| Result | GA | DE | PSO |
| :---: | :---: | :---: | :---: |
| Table 6.4 | $0 / 140$ | $126 / 140$ | $14 / 140$ |
| Table 6.5 | $0 / 140$ | $117 / 140$ | $23 / 140$ |
| Overall Total | $0 / 280$ | $243 / 280$ | $37 / 280$ |

Thus, the overall results for CPU time of GA, DE and PSO are reflected in Table 6.9. The overall number of results given the Table 6.6 and Table 6.7 is also 280 .

Table 6.9: Overall results for CPU time of GA, DE and PSO

| Result | GA | DE | PSO |
| :---: | :---: | :---: | :---: |
| Table 6.6 | $140 / 140$ | $0 / 140$ | $0 / 140$ |
| Table 6.7 | $140 / 140$ | $0 / 140$ | $0 / 140$ |
| Overall Total | $280 / 280$ | $0 / 280$ | $0 / 280$ |

Based on the results in Table 6.8, DE obtained the least average optimised surface error for most of the experiments which is $243 / 280$ (126/140 for the same grid size, 117/140 for different grid size). Meanwhile, PSO achieved the second-most total number of least average optimised surface error which is $37 / 280$ (14/140 for the same grid size, $23 / 140$ for different grid size) as shown in Table 6.8. In contrast, GA achieved 0/280 least surface error ( $0 / 140$ for the same grid size, $0 / 140$ for different grid size).

Based on the results in Table 6.9, GA achieved 280/280 least average CPU time (140/140 for the same grid size, 140/140 for different grid size). Meanwhile, both DE and PSO achieved 0/280 least average CPU time (0/140 for the same grid size, 0/140 for different grid size).

In terms of the average optimised surface error, DE performed better than GA and PSO because the individuals in DE can easily explore the new region in the search space [149] and converged to the optimal solution better than GA and PSO. Besides, DE performed better than GA because mutation operation in DE was performed on the target vector at every iteration while the
mutation operation in GA was performed according to the mutation probability applied [113]. Thus, DE can maintain the population diversity better than GA. Furthermore, the difference between the mutation operation in DE and GA is that the mutation operation in DE is the outcome of arithmetic combinations of individuals while the mutation operation in GA is the outcome of small perturbations to the genes of an individual [151]. In terms of the CPU time, DE performed slower than GA because each target vector in DE was compared with the trial vector to produce a new target vector at each iteration.

The PSO can perform better than DE for certain cases because technique with better exploration property such as DE is more efficient in finding the optimal solution when the size of CN is small. As the size of the CN increases, technique with a good balance between exploration and exploitation property such as PSO with velocity clamping is better in finding the optimal solution. PSO with velocity clamping can control the position and velocity of each particle and it was developed to make a good balance between exploration and exploitation [152]. The PSO has better accuracy for highdimensional problems [150]. The PSO performed slower than DE because the particles in PSO must update their position and velocity both locally and globally at each iteration [142].

GA performed the worst because there are only two new individuals that can be introduced at each iteration [142]. Two new individuals are introduced when both selected parents achieved a higher optimised surface error than their offspring [153]. Meanwhile, $n$ new individuals and particles
are introduced in DE and PSO at every iteration. Thus, DE and PSO are better than GA in finding the optimal solution. GA performed the fastest despite having a greater number of operations involved such as selection, crossover, mutation and replacement [141] because not every individual was updated at each iteration unlike the DE and PSO in which every individual in DE and particle in PSO were updated at each iteration. Thus, GA performed the best in terms of the CPU time followed by the DE and PSO. The information can be referred in Appendix M and Appendix N.

In short, DE is the best optimisation technique because it can achieve the least optimised surface error for most of the experiment and generate the output at a moderate CPU time.

### 6.4 Summary

Optimisation methods such as GA, DE and PSO can be implemented to optimise the control points of the improved NURBS surface approximation approach. The DE performed the best followed by PSO and GA. However, the PSO can perform better than DE for certain cases. When the size of CN is small, optimisation method with exploration property such as DE is more efficient in finding the optimal solution, whereas optimisation method with both exploration and exploitation property is better in finding the optimal solution when the size of the CN is large. The GA took the shortest CPU time among the techniques, followed by DE and PSO. Therefore, the results show that the optimisation methods can optimise the surface produced by the improved approach and be used in surface reconstruction.

## CHAPTER 7

## CONCLUSION AND FUTURE WORKS

### 7.1 Conclusion

A model inspired by Lim and Haron [25] dubbed Double Net Self-Organising Map (DNSOM), was proposed through the merging of two 2-D SelfOrganising Map (SOM). The model was designed to organise the unstructured data and to regain the connectivity information of the data. The model overcomes the drawbacks of 2-D SOM, 3-D SOM and Cube Kohonen SOM (CKSOM). Besides, the model organised the unstructured data successfully. It was able to preserve the topology of the data as it achieved the lowest Topographic Error (TE) compared to all the SOM models. Additionally, the DNSOM model can produce the correct surface with fewer neurons compared to the CKSOM model and the length and width of its grid can be tuned with different values. Besides, the improved NURBS surface approximation approach was integrated successfully on the DNSOM surfaces data and four equations were derived to identify the four corners of the CNs and DNSOM surfaces data. The improved NURBS surface approximation approach can generate the improved NURBS surfaces without gaps. The Chord Length method is the best method because it achieved the least surface error for most of the experiments. GA performed the best in term of CPU time although it has more operations compared to DE and PSO. Meanwhile, PSO achieved the highest CPU time among the optimisation methods.

### 7.2 Contributions

The ability of the DNSOM model to organise the unstructured data of talus bone would contribute to the field of medical imaging in a way that the model can help the medical practitioner to create an artificial talus bone for patients whom their talus bone is damaged. The model can also be utilised in reverse engineering to recover the digital file of an object. Hence, the designers can save their time from redesigning the object from scratch. In addition, it does not require huge amount of data for training. Thus, it can reconstruct the surface of an object faster. Besides, three equations were derived based on the model so that the researcher can identify the NON, NOV and NOR for the model and can construct the model based on the equations. Furthermore, the improved NURBS surface approximation approach can generate multiple surfaces without gaps and four equations were derived to identify the four corners of the DNSOM surfaces data and CN. Besides, this research proves that the concept of applying the GA, DE and PSO to optimise the control points of the improved NURBS surface approximation approach is applicable.

### 7.3 Limitations

Although the DNSOM model can organise the unstructured data, it suffers from several limitations. It has higher QE than 3-D SOM and CKSOM models and it fails to reconstruct the ear of the Stanford bunny data correctly. Besides, the height of the DNSOM model is fixed. The lack of flexibility in setting the height of the model may cause the model to be inappropriate to present longer objects.

### 7.4 Future works

Future work can consider minimising the QE with optimisation methods and enhancing the Detecting Neighbours (Section 4.2.4) for the adaptation process as demonstrated in [24] to overcome the limitations mentioned previously. Besides, more complex data such as the happy Buddha, dragon and armadillo from can be used to test the performance of the model. Other parameterisation methods such as the hybrid method [87], deep learning method [143] and dynamic centripetal method [89] can also be applied to further examine their influence on the improved NURBS surface approximation approach. The optimisation techniques can also be used to optimise the weights of the improved approach. Furthermore, optimisation techniques such as Bat algorithm [144] and Firefly algorithm [145] can also be used to optimise the control points of the improved approach and examine the performance between the techniques.
